## II. Glossary

The following list of abbreviations excludes one-time uses of common gene names and several in-text abbreviations found in tables of results, where the expanded term and abbreviation are described within the same section of the table.

25OHD	25-hydroxyvitamin D
aRR	Adjusted relative risk
ABP	Androgen binding protein
ADHD	Attention deficit hyperactivity disorder
ALT	Alanine aminotransferase
AST	Aspartate transaminase
ATPase	Adenosine triphosphate enzymes
BMD *	Bone mineral density
BMD *	Benchmark dose (NOTE: the same abbreviation is used in two different ways throughout the document. The context of the differing uses is always clear. This was intentionally done because both uses are established in the medical and statistical literature, respectively.)
BMC	Benchmark concentration
BMCL	Benchmark concentration lower bound
BMDL	Benchmark dose lower bound
BMI	Body mass index
BMR	Benchmark response
CADTH	Canadian Agency for Drugs and Technologies in Health
CFI	Community Fluoridation Index
CI	Confidence interval
CKD	Chronic kidney disease (CKDu, of uncertain etiology)

CVD	Cardiovascular disease
CWF	Community water fluoridation
DA	Dopamine
DDE	Developmental defects of enamel
DF	Dental fluorosis
DMA	Dimethylarsinic acid
D-R	Dose-response
DSM	Diagnostic and Statistical Manual of Mental Disorders
DW	Drinking water
DWL	Drinking water levels
E2	Estradiol
ER	Endoplasmic reticulum (i.e., ER stress)
ESR $\alpha$	exposure and estrogen receptor alpha
FSH	Follicle stimulating hormone
FT	Free T4 index
GCI	General Cognitive Index
GIT	Gastrointestinal Tract Disorder
HBV	Health-based Value
HR	Hazard ratio
IARC	International Agency for Research on Cancer
IQ	Intelligence quotient
IQR	Interquartile range
LH	Luteinizing hormone
LOAEL	Lowest observed adverse effect level
MAC	Maximum acceptable concentration

MUFcr	Creatinine adjusted maternal urinary fluoride
NaF	Sodium fluoride
NASEM	National Academy of Sciences, Engineering, and Medicine
NHMRC	Australian National Health and Medical Research Council
NOAEL	No observed adverse effect level
NR	Not reported
NTP	National Toxicology Program
OCDO	Office of the Chief Dental Officer
OHAT	Office of Health Assessment and Translation (US National Toxicology Program)
OR	Odds ratio
P	Progesterone
PMI	Primary methylation index
POD	Point of departure
PPM	Parts per million
PTH	Parathyroid hormone
SD	Standard deviation
SDQ	Strengths and Difficulties Questionnaire
SE	Standard error
SHBG	Sex hormone-binding globulin
SMI	Secondary methylation index
SR	Systematic review
SUA	Serum uric acid
TSH	Thyroid-stimulating hormone
TT3	Total triiodothyronine
TT4	Total thyroxine

Tvol	Thyroid volumes
UF	Uncertainty factor
UF <sub>SG</sub>	Urinary fluoride adjusted for specific gravity
WQP	Water Quality Program

### III. Executive summary

Health Canada's current guideline technical document for fluoride in drinking water <sup>[1]</sup> derives a health-based value (HBV) of 0.9 mg/L (considered to be protective against all potential adverse health effects) and presents an optimal concentration for dental health of 0.7 mg/L for communities that choose to fluoridate their water. At present, the maximum acceptable concentration (MAC) for fluoride in drinking water of 1.5 mg/L is based on drinking water treatment considerations. The Water Quality Program (WQP) at Health Canada recently underwent a robust prioritization process for drinking water chemicals. Fluoride was identified as a high priority for review due to both new scientific publications and provincial and territorial needs. Moderate dental fluorosis is the key endpoint for Health Canada's current HBV; however, there is growing evidence that potential neurotoxic effects may occur at lower levels than previously thought. The mandate of the current review was to provide a critical evidence synthesis for the purposes of updating the current HBV for fluoride in drinking water.

This current review (the "RSI review") represents an update of several prior reviews on multiple health endpoints that were published by CADTH 2019 <sup>[2, 3]</sup> (human studies), Health Canada 2010 <sup>[1]</sup> (animal and in vitro studies), and NTP 2016 <sup>[4]</sup> (specifically on cognitive and neurotoxic endpoints over multiple streams of evidence). The RSI review consisted of a systematic literature search that was conducted between February 10 – 12, 2020 for all eligible types of publications. An update of this search for all potential adverse health effects was conducted on July 21 – 22, 2021, with the exception of reviews and in vitro evidence. A third update of the search was conducted on February 2, 2023 for studies on two endpoints: dental fluorosis and effects on IQ scores. The systematic search of human and animal evidence was conducted in accordance with the PRISMA guidelines, following the specific guidance provided by the Cochrane Collaboration, and covered 10 bibliographic databases, 6 clinical trial registries, and major grey literature sources. The quality of included human and animal studies was assessed using the US National Toxicology Program's OHAT risk of bias tool <sup>[5, 6]</sup>, which includes seven domains of bias against which each study was assessed for quality of evidence. Mechanistic and in vitro evidence from systematic and authoritative reviews were critically assessed and summarized.

The RSI search for human evidence identified 89 studies that were conducted between 2016-2023, including cross-sectional (n=70), ecological (n=4), cohort (n=9), case-control (n=4)

studies, and abstracts (n=2). Studies were conducted in China (n=18), India (n=17), USA(n=9), Mexico (n=8), Canada (n=7), Brazil (n=5). Three studies were conducted in Pakistan and Sri Lanka, two in each of Ethiopia and Malaysia, and 1 study in each of Egypt, Indonesia, Iran, Ireland, Jordan, Lithuania, Peru, Saudi Arabia, Scotland, South Korea, Spain, Sudan, Sweden, Thailand, Ukraine. Most of the studies examined fluoride exposure in drinking water (n=57) or ground water (n=17). The examined populations were children and/or adolescents (n=54), adults (n=15), mixed (n=19 including 6 that enrolled mother-child pairs), and unreported population age (n=1).

NTP published updated draft reports in 2020 <sup>[328]</sup> and in 2022<sup>[420]</sup> after independent reviews conducted by the National Academy of Sciences, Engineering, and Medicine (NASEM)<sup>[7]</sup>. This update included a review of epidemiologic evidence on fluoride-related cognitive effects. The NTP results and conclusions are discussed in the context of evidence reviewed in the current report.

One hundred and ninety-nine original animal studies were retained for data abstraction and detailed analysis. Using a tiered approach of relevance and quality, 35 tier-1 studies were included in the evidence synthesis. These studies covered the effect of fluoride on several endpoints of concern over a range of drinking water fluoride concentrations for sub chronic to chronic durations; the majority of the studies investigated neurological, developmental, or reproductive outcomes. Ten reviews were identified that summarized effects of fluoride at cellular levels and its mechanism of action. These reviews indicated that fluoride caused changes in oxidative stress levels, gene expression levels, mitochondrial dysfunction, and eventual cell death through various molecular pathways and mechanisms, including ER stress, Na/K+ ATPase pathway, apoptosis, inflammatory pathways, or death receptor-mediated pathways. However, the evidence was considered too non-specific to necessarily support particular mechanisms that could be attributed to specific health outcomes.

Based on the entire body of evidence reported from human, animal, and in vitro streams to date, and relying predominantly on studies of high or acceptable quality, four endpoints were chosen as candidates for further assessment using the Bradford Hill considerations <sup>[8]</sup> on causality. These endpoints included cognitive (IQ) effects in children, thyroid dysfunction, kidney dysfunction, and sex hormone disruptions. The evidence supports a conclusion that fluoride exposure reduces IQ levels in children, likely at exposure levels close to those

currently seen in Canadian drinking water. The evidence also moderately supports the link with thyroid dysfunction, and weakly supports the link with kidney dysfunction. Evidence was considered limited to support a link between fluoride and sex hormone disruptions.

No points of departure (POD) were derived for thyroid dysfunction, kidney dysfunction, and sex hormone disruption because more evidence is needed to support the causal link of fluoride exposure and these health endpoints.

The US EPA, in its 2010 report on non-cancer effects of fluoride, used data from Dean (1942) to derive a benchmark concentration for severe dental fluorosis. In the current report, based on the selection of moderate dental fluorosis as an endpoint of concern, all epidemiologic studies published since Dean (1942) were considered as possible key studies for benchmark dose modelling. Based on several considerations, including risk of bias, sources of fluoride, and adequacy of data for modelling, Dean (1942) was still found to be a preferable key study. In the current work, several models were fit based on Dean's fluorosis index (DFI), using 3+ as the cutoff to combine moderate (DFI=3) and severe (DFI=4) categories of fluorosis. Bayesian model averaging was used to derive the lower bounds of the benchmark concentration (BMCL) of 1.56 mg/L for a benchmark response (BMR) of 1%, 2.13 mg/L for a BMR of 5%, and 2.46 mg/L for a BMR of 10%.

In considering cognitive effects in children, specifically for IQ reductions, there remains significant uncertainty as to the POD. While statements from draft NTP reports (2020,2022) concluded that evidence for associations below 1.5 mg/L was less consistent than above 1.5 mg/L, a recent benchmark dose analysis (Grandjean et al., 2022) using high-quality cohort data (from MIREC and ELEMENT) with individual-level measures provided maternal urinary fluoride benchmark concentrations far lower than 1.5 mg/L for a 1-point IQ reduction. For the pooled cohort studies, for both sexes at the youngest ages, the BMCL was 0.179 mg F/L in drinking water (when converted from maternal urinary fluoride) with a linear model, but various models produced estimates that varied by more than 9-fold (ranging from 0.077 mg F/L to 0.753 mg F/L drinking water). Considering the overall evidence for an effect of fluoride on IQ reduction in children, the POD for IQ may provisionally be considered as 1.5 mg F/L, while acknowledging that credible evidence exists to support that the POD may be lower than this concentration (based on cohort data). However, the majority of studies to date are cross-

sectional studies of low quality, and there is uncertainty in the shape of the dose-response curve at low levels of exposure to fluoride.

Since the POD of 1.56 mg F/L for moderate and severe dental fluorosis is based on high-quality population-based data in the target population (children), with less concern about other sources of ingested fluoride, a minimal adjustment factor could be entertained in deriving an HBV based on fluorosis. However, with currently available evidence suggesting that fluoride leads to reductions in children's IQ – arguably a more severe adverse health outcome than moderate dental fluorosis – the possibility of cognitive effects in children should be taken into account in setting an HBV for fluoride in drinking water. As the POD for IQ reduction is not yet well defined, the POD of 1.56 mg F/L for moderate dental fluorosis may be preferred as a starting point for deriving the HBV. To allow for protection against potential cognitive effects, an additional overall database uncertainty factor could be applied to this POD. As additional information on the association between fluoride in drinking water and reduction in children's IQ becomes available, the choice of the most appropriate endpoint on which to base the POD to serve as the starting point to deriving an HBV for fluoride can be revisited.

## IV. Background

The Water Quality Program (WQP) at Health Canada recently underwent a robust prioritization process for drinking water chemicals. Fluoride was identified as a high priority for review due to both new scientific publications and provincial and territorial needs.

Moderate dental fluorosis is the key endpoint for Health Canada's current Health-based Value (HBV) in drinking water. Fluoride has been associated with various adverse health effects, including neurotoxicity. There is growing evidence that potential neurotoxic effects may occur at levels of exposure that are environmentally relevant and at lower levels than previously thought. Although Canada is not known to have wide geographic areas with elevated fluoride concentrations, fluoride may be found in Canadian water sources at levels of exposure cited in the new studies showing neurotoxic effects in children.

Health Canada's WQP published a review of the health effects of exposure to fluoride in drinking water in 2010, as part of the update to the Guideline for Canadian Drinking Water Quality for Fluoride <sup>[1]</sup>. This publication discussed all relevant scientific information available at the time of the review, as well as recommendations from an expert panel on fluoride. The panel was convened by HC in 2007 to provide recommendations related to fluoride in drinking water, including both potential adverse health effects and the public health benefit of preventing dental caries. Health Canada's Office of the Chief Dental Officer (OCDO) was part of the panel and reviewed dental effects of fluoride. The OCDO accepted the expert advice on the optimal level for fluoride in drinking water. The Health Canada guideline technical document <sup>[1]</sup> for fluoride includes a derivation of an HBV of 0.9 mg/L (considered to be protective against any potential adverse health effects), with a rationale provided by the Federal-Provincial-Territorial Committee on Drinking Water to risk manage at a maximum acceptable concentration (MAC) of 1.5 mg/L for fluoride in drinking water. Decisions to fluoridate drinking water are made at the municipal and/or provincial/territorial level.

The OCDO recently commissioned a third-party (the Canadian Agency for Drugs and Technologies in Health, CADTH) comprehensive review of the evidence and other considerations related to community water fluoridation (CWF), including the effectiveness and health impacts of CWF and ethical considerations. The results of the CADTH review <sup>[2, 3]</sup> were published on February 8th, 2019. The report acknowledges that dental fluorosis prevalence

may increase with increasing water fluoride levels, even though dental fluorosis of “aesthetic concern” among Canadian children is rare. Conclusions on the health impacts of CWF from this report are of qualitative nature and cannot be used in the context of a quantitative risk assessment, where the goal is to determine a “safe” level of exposure to a substance. The CADTH review was focused on community water fluoridation around 0.7 mg/L, and not the range of naturally occurring levels, which could be much higher (>1.5 mg/L). In order to determine an HBV and MAC, the WQP needed to build on the CADTH review to establish at which level in drinking water fluoride may be associated with various health outcomes, including neurotoxicity.

In recognition of recent research findings, the results of the prioritization exercise and the public interest in this issue, it was proposed that the state of the science of the health effects of fluoride in drinking water be re-examined. The current report consists of a critical review of the scientific evidence on potential health effects of fluoride in drinking water, complementary to the CADTH review.

The objective of this review was to assess the current body of evidence to support the update of Health Canada’s guideline for fluoride levels in drinking water, as well as inform any potential revision of the HBV. The work involved conducting a critical review of recently published evidence from human, animal, and in vitro studies.

## **V. Literature review methods**

The current project (the “RSI review”) sought to update recent reviews with the following scope:

- For endpoints on dental fluorosis, cancer, bone/skeletal toxicity, developmental/reproductive toxicity, endocrine toxicity (including thyroid effects), immunotoxicity, genotoxicity and all other potential adverse effects), an update was undertaken of human evidence (CADTH 2019 <sup>[2]</sup>), animal and in vitro evidence (Health Canada 2010 <sup>[1]</sup>).
- For endpoints on neurotoxicity and other cognitive domains, an update was undertaken on human evidence (CADTH 2019a <sup>[3]</sup>), animal evidence (NTP 2016 <sup>[4]</sup>), and in vitro evidence (Health Canada 2010 <sup>[1]</sup>).

The eligibility criteria for inclusion in the RSI review included all original studies and reviews published between 2016 to present, which examined the association of exposure to fluoride in drinking water (fluoridation, or naturally occurring fluoride) with any adverse health outcomes. Exclusion criteria contained studies and/or reviews that were examined in CADTH 2019 reports [2, 3], published prior to 2016, examined other fluoride formulations or mixtures, assessed dental outcomes other than dental fluorosis, reported irrelevant assessments (e.g., hazard quotient), or published in a non-Latin language. Full-text references that could not be retrieved, or other irrelevant study types such as commentaries, editorials, case reports/case series, books and general informational materials were also excluded.

## **Human evidence**

### **Previous reviews of human evidence**

The RSI review is an update of two prior reports published by the Canadian Agency for Drugs and Technologies in Health (CADTH) in 2019 [2, 3]. The first review by CADTH [2] was an update of the systematic review conducted by the Australian National Health and Medical Research Council (NHMRC) in 2016 [9, 10], and investigated three research questions, where only the third was found to be relevant to the RSI review: “What are the negative effects of community water fluoridation (at a given fluoride level) compared with non-fluoridated drinking water (fluoride level < 0.4 ppm) or fluoridation at different levels on human health outcomes?”.

The literature search, which was developed using both controlled vocabulary and keywords, was peer-reviewed, and conducted by an information specialist. Multiple databases were searched to capture potentially relevant studies from 2014-2018. No search restrictions by language or methodology were applied. Search of grey literature sources, web-based materials, and reference lists of key articles were conducted. References captured by the first CADTH report [2] search underwent level 1 (title and abstract) and 2 (full-text) screening by two independent reviewers. In total, 41 studies were identified in addition to the 41 studies already included by the NHMRC 2016 report [9, 10].

The second report by CADTH 2019a [3] investigated a related but more focused research question: “What are the neurological or cognitive effects of community water fluoridation, compared with non-fluoridated or different fluoride levels in drinking water, in individuals less

than 18 years of age?”. The literature search examined human studies from multiple databases between 2017-2019. No limitation by study type was applied. References identified by the second CADTH review [3] search were screened by a single reviewer. Studies already included in the prior CADTH 2019 report [2] were excluded from the review. In total, only a single prospective cohort study was identified as relevant. As part of the RSI review exclusion criteria, all references examined by either one of the 2 CADTH reports [2, 3] were not included in the RSI review.

### **The RSI search strategy: Identification of new human evidence**

In conducting this updated review, RSI examined more recent human evidence on the association between fluoride in drinking water with a wide range of endpoints, which was published between 2016 – present and not included in either of the 2019 reports by the Canadian Agency for Drugs and Technologies in Health (CADTH) on neurocognitive [3], and dental and other endpoints [2].

A comprehensive, multi-step search strategy was implemented to identify review articles and original human studies that examined the association between exposure to fluoride in drinking water with the risk of adverse health outcomes. No filters were applied to limit the search output. The search was conducted in accordance with PRISMA guidelines (Preferred Reporting Items for Systematic Reviews and Meta-Analyses), and following the specific guidance provided by the Cochrane Collaboration [11].

The search strategy for human studies was designed and implemented between February 10-12, 2020 by two reviewers. An update for original studies on all adverse health effects was conducted on July 21, 2021.

As requested by Health Canada, an updated literature search was conducted for intelligence quotient (IQ) and dental fluorosis adverse health effects. The search of bibliographic databases was performed on February 2, 2023. Search results were compiled in EndNote, and duplicates were removed. Level 1 (title and abstract) and 2 (full-text) screening were independently completed by two reviewers, and any conflicts were resolved via discussion. Data abstraction and quality assessment were conducted by a single investigator and verified by a second investigator.

RSI searched 10 bibliographic databases, 6 clinical trial registries to identify relevant literature using specific keywords without applying any filters. See Section 1 of the Supplementary Material for details on the searched sources, used terms, and search output. RSI also searched 18 major grey literature sources such as relevant national and international authoritative and technical health agencies, academic dissertations, major scientific hubs, and international conference proceedings. Additionally, bibliographies of examined studies were inspected for additional relevant studies not already identified via the original search.

Date of updates of literature search	Evidence streams and target endpoints
February 10, 2020	Summary of <i>human, animal and in vitro</i> evidence from reviews and original studies
July 21, 2021	Systematic review of animal evidence on all endpoints
July 21, 2021	Systematic review of epidemiologic evidence on endpoints: sex hormone dysfunction, ADHD, dementia, liver dysfunction, memory loss, preterm births, genotoxicity, ultrastructural kidney changes, BMI, childhood obesity, selected eye diseases, general health, trouble working, suicide, arsenic methylation, skeletal fluorosis, thyroid dysfunction, bone density and quality, bone cancer, hip fracture, atherosclerosis, myocardial infarction, kidney dysfunction, headache, diabetes mellitus, non-skeletal manifestations of fluoride toxicity, and sleep-related outcomes
February 2, 2023	Systematic review of epidemiologic evidence on endpoints: cognitive (IQ), dental fluorosis

Identified references from all sources were collated using the EndNote<sup>[12]</sup> reference management application. EndNote was used to identify potential duplicates, with manual resolution employed to remove additional actual duplicates. Screening of titles and abstracts (level 1) and full-text examination (level 2) were performed independently by two reviewers to

identify studies eligible for inclusion in the review. The review was completed through a multi-level assessment process, using the Distiller SR software [13].

Conflicts identified in each step were resolved via consensus prior to moving to the next level. In the event where multiple publications report on an original study or trial, only the primary publication was assessed in the review.

The RSI literature search considered original published reviews to assess whether they would suffice as updates to the reviews by CADTH, Health Canada, or NTP. Reviews were screened using three criteria:

1. Does the review have sufficient description of its methodology? (Yes, but only if 1 or more databases were searched)
2. Is the review peer-reviewed (e.g., journal publication) or prepared by an authoritative body (e.g., IARC) or high-profile research agency?
3. Does the review present a clear overall conclusion on the body of literature examined for each outcome of interest?

Reviews with a “Yes” response to all questions were considered potentially eligible.

### **Data abstraction**

Data abstraction spreadsheets were developed using Microsoft Office Excel, and used to abstract the following information: study design, study population characteristics, exposure and outcome assessment, results and authors’ reported conclusion. Key characteristics of the included human studies are summarized in Table 3 in this report and provided in full details in Section 3 of the Supplementary Material.

### **Statements on the assessment of the evolving evidence**

For each endpoint, RSI classified the evolving evidence into one of the following categories:

- **Sufficient:** Most of the evidence consistently supports no association or a confirmed association, based on several studies of high to acceptable quality that have been published on the relevant fluoride and health endpoint.

- Limited: Some evidence in support of an association, based on only a few studies of high to acceptable quality that have been published on the relevant fluoride and health endpoint.
- Inconsistent: Mixed evidence in support of an association, based on studies of high to acceptable quality that provided conflicting evidence on the relevant fluoride and health endpoint.
- Insufficient: Scarce or unclear evidence in support of an association, based on too few studies of high to acceptable quality that have been published on the relevant fluoride and health endpoint.

### **Animal evidence**

In conducting this review, RSI examined animal evidence on the association between fluoride in drinking water with a wide range of endpoints, from original studies published after 2006 and not included in the 2010 report by Health Canada <sup>[1]</sup> on several endpoints including neurotoxicity and neurobehavioral effects.

RSI implemented a comprehensive, multi-step search strategy to identify review articles and original human studies that examined the association between exposure to fluoride in drinking water with the risk of multiple adverse health outcomes. No filters other than “animals only” were applied to limit the search output. The search was conducted in accordance with PRISMA guidelines, and following specific guidance provided by the Cochrane Collaboration <sup>[11]</sup>.

The search strategy for animal studies was designed and implemented between March 14-18, 2020 by two reviewers. An update for original studies was conducted on July 21, 2021. RSI searched 10 bibliographic databases to identify relevant literature using specific keywords without applying any filters. See Section 1 of the Supplementary Material for details on the searched sources, used terms and search output.

RSI also searched 18 major grey literature sources such as relevant national and international authoritative and technical health agencies, academic dissertations, major scientific hubs, and international conference proceedings. Additionally, an inspection of the bibliographies of

examined studies was conducted for additional relevant studies not already identified via the original search.

Identified references from all sources were collated using the EndNote<sup>[12]</sup> reference management application. EndNote was used to identify potential duplicates, with manual resolution employed to remove additional actual duplicates. Screening of titles and abstracts (level 1) and full-text examination (level 2) were performed independently by 2 reviewers to identify studies eligible for inclusion in the review. The review was completed through a multi-level assessment process, using the Distiller SR software<sup>[13]</sup>. Conflicts identified in each step were resolved via consensus prior to moving to the next level.

Data abstraction spreadsheets were developed using Microsoft Office Excel, and used to abstract the following information: study design (animal model, age, sex, number of animals, chemical salt, guideline compliance), treatment (dose levels, route of administration, exposure duration, dosing frequency), endpoint information, statistical methods, outcomes assessed, effects levels (LOAEL, and NOAEL [no-observed-adverse-effect level]), dose response trend, strengths and limitations, and authors conclusions.

Due to the large volume of potentially eligible animal studies (~200), a tiered approach was employed to determine and select studies with “key” information relevant for the current objectives. This approach categorized studies into three tiers with tier-1 containing all “key” information for the review, and tier-2 containing supporting information. Furthermore, studies in tier-1 underwent full data extraction and quality assessment. Tier-1 studies tended to be guideline studies (OECD (office of economic collaboration and development), GLP (good lab practices)) that assessed oral route of exposure at relevant concentrations ( $\leq 20$ ppm). A limited data extraction with no quality assessment was performed for studies placed in tier-2. No data abstraction or quality assessment was undertaken for tier-3 studies (See Section 4 of the Supplementary Material). In this approach, each study that passed level 2 screening was reviewed for the following “key” information and placed in the appropriate tier.

- whether the study tested more than one fluoride exposure concentration (to understand dose-response relationships)
- at least one exposure concentration tested was below 20 ppm (to examine effects at environmentally relevant exposures)

- whether primary objective was fluoride toxicity (to eliminate intervention studies such as studies with focus on exposures that may enhance or protect against fluoride toxicity)
- whether the study evaluated solely mechanistic endpoints (not purely a mechanistic study)
- whether the study had been already evaluated by an authoritative body

These considerations for the tiered approach are outlined in Figure 1.

Criteria	Response		Assessment	Tier
Is dose - response information available	Yes	No	All green	1
At least one test conc ≤ 20 ppm	Yes	No	If not in Tier 1, but Yes for D-R information or fluoride conc ≤ 20 ppm	2
Is primary objective fluoride toxicity	Yes	No		
Only mechanistic outcomes assessed	Yes	No	If No for D-R information AND No for fluoride conc ≤ 20 ppm	3
Included in an authoritative review	Yes	No		

Figure 1: Considerations for tiered approach for animal studies

### In vitro evidence

The in vitro evidence stream was comprised of a review of reviews. Authoritative reviews were first identified as those published after the 2010 Health Canada report and those having sections that pertained to mechanistic or in vitro evidence with no restriction on the endpoint being considered in the review. Narrative summaries were then developed for each key mechanism of action related to fluoride. A general description was provided for the mechanism of action and how it related to selected health endpoints. This was supplemented with a table of recent studies and a brief extraction of characteristics of those studies.

### Risk of bias assessment

The quality of included human, animal, and in vitro studies was assessed using the OHAT risk of bias tool, designed by the US National Toxicology Program [5, 6]. This tool enlists 10 parameters across 7 domains against which each study is assessed for quality of provided evidence. For every parameter, each study is assessed into one of four levels based on their

risk of bias: definitely low risk of bias (++), probably low risk of bias (+), probably high risk of bias (–), and definitely high risk of bias (– –).

Based on the assessment, each study is assigned a score of 1, 2, or 3 corresponding to high, acceptable, or low level of quality, respectively. Score 1 implies that a study must be rated as “definitely low” or “probably low” risk of bias for key elements AND have most other applicable items answered “definitely low” or “probably low” risk of bias. Score 3 implies that a study must be rated as “definitely high” or “probably high” risk of bias for key elements AND have most other applicable items answered “definitely high” or “probably high” risk of bias. Score 2 is reserved for studies not meeting the requirements for scores 1 or 2 on the risk of bias assessment. A summary of the risk of bias assessment of the included studies is shown in Table 4 (human studies) and Table 10 (animal studies) in this report. Full details of the assessment of human studies provided in Section 3 of the Supplementary Material.

## **VI. Literature review results**

### **Human evidence**

The search strategy resulted in retrieval of 4,141 records, including 3,783 records from bibliographic databases and clinical trial registries, 358 records from major grey literature sources. Electronic de-duplication resulted in removal of 1,397 records studies, leaving 2,774 studies for title and abstract screening (level 1). Upon excluding 2,990 irrelevant studies, there were 409 studies left for full-text examination (level 2). This examination led to the exclusion of an additional 344 references for not matching our inclusion/exclusion criteria. RSI were finally able to retain 65 original studies for further analysis.

The 2023 search for new evidence for exposure to fluoride in drinking water and either effects on IQ or on dental fluorosis, identified 879 new studies since the last update in 2022. Upon removing duplicates and studies examined in the 2022 RSI report, a total of 343 studies underwent independent and duplicate title, abstract and full-text examination, leading to identification of 24 new studies, raising the number of retained studies to 89. A detailed PRISMA flow diagram <sup>[14]</sup> showing the selection process for human studies for the first and second searches only is shown in Figure 2. A summary of rationale for study exclusion for the first two searches as well is summarized in Table 1, and detailed in Section 2 of the

Supplementary Material. Studies retained for qualitative analysis with a listing of examined endpoints are shown in Table 2.

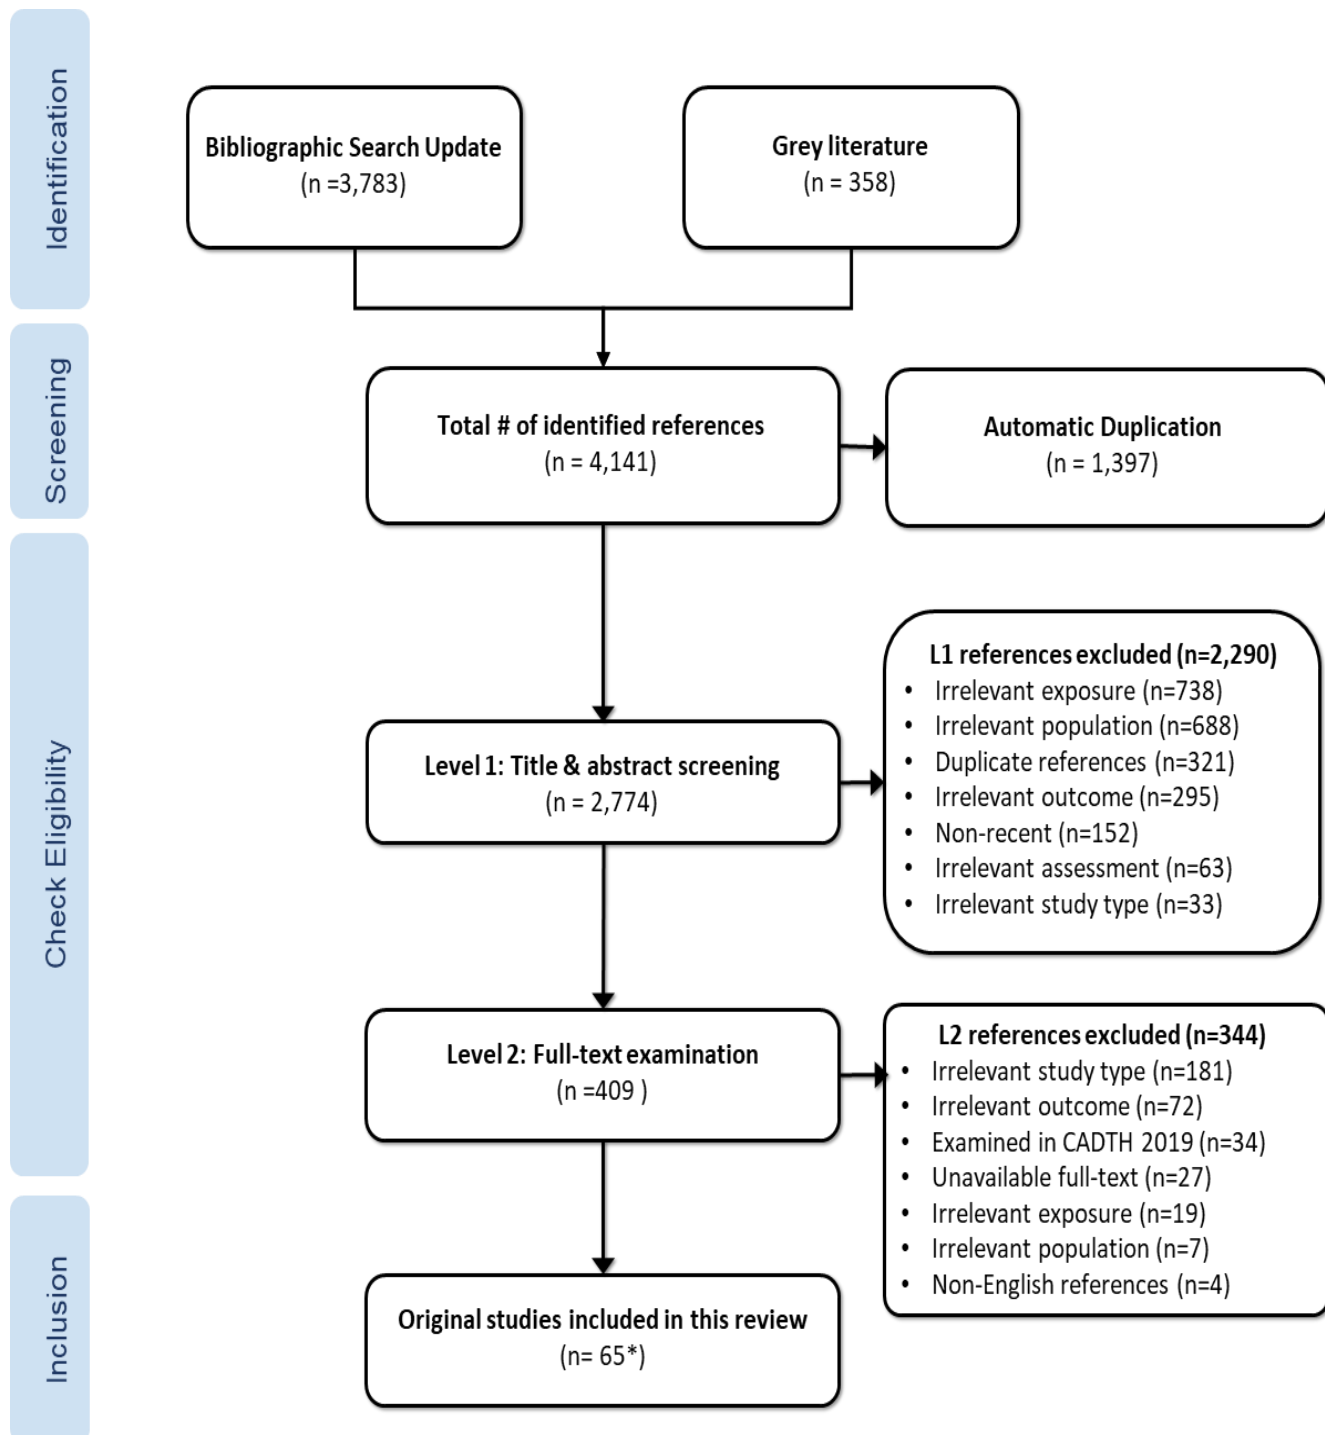

Figure 2: PRISMA flow diagram for human studies

\* These 65 references include 2 relevant abstracts

Table 1: Studies excluded at levels 1 and 2 by reason for exclusion

Level	Reason for exclusion	References
<b>Level 1</b> <i>(Title and abstract screening)</i> 2,290	Irrelevant exposure (other type of fluoride/water)	738
	Irrelevant population (non-human studies)	688
	Duplicate references	321

	Irrelevant exposure (other type of fluoride/water)	19
	Irrelevant population (non-human studies)	7
	Non-English references	4

The 89 included original studies examined a wide range of adverse health effects due to exposure to fluoride in water, particularly dental fluorosis (33 studies) and neurocognitive (28 studies), bone and skeletal (9 studies), and endocrine and urogenital outcomes (8 studies, each). Table 2 provides a summary of all identified fluoride-related adverse health outcomes. Reviews identified during the RSI literature search are summarized in Table 5, but not evaluated further.

## Characteristics of included human studies

Out of 89 original studies retained for qualitative analysis, 70 (79%) were cross-sectional in design, 9 were cohort studies [21, 37, 40, 58, 65, 71, 409, 419], 4 were case-control studies [33, 34, 44, 70], 4 were ecological [35, 43, 64, 76], and 2 were abstracts only [15, 16]. All of the retrieved studies were published between 2016 and 2023. The sampling time frame included variable time intervals between 1992-2021, with 29% of studies that did not report a time frame.

Eighteen studies (20%) were carried out in China and 17 in India (19%), with USA, Mexico and Canada involved in 9 (10%), 8 (9%) and 7 (8%) studies, respectively. Sixty-five percent of studies examined fluoride exposure in drinking water (n=57), or 19% in ground water (n=17), compared to urine/MUF or serum with 11% (n=10) and 1% (1), respectively. Three studies reported no source of fluoride exposure.

The examined population were comprised of children and/or adolescents in 54 studies (61%), adults in 15 studies (17%), mixed populations in 13 studies (15%), and mother-child pairs in 6 studies (7%). The number of study participants ranged from as low as n=83 to as high as 6,914,124 persons. The majority of studies included both men and women (n=78), whereas 3 studies involved only men, 2 involved only women, and 6 studies examined mother-child pairs.

A summary of major study characteristics is shown in Table 3. The table also provides summaries of findings for each study, where positive association refers to increased adverse effects with increasing fluoride exposure, and negative association refers to decreased adverse effects with increasing fluoride exposure. More detailed characteristics of individual studies are provided in Section 3 of the Supplementary Material.

Table 3: Characteristics of included human studies<sup>1</sup>

<b>Feng 2022</b> <sup>[417]</sup> <sup>2</sup>				

<sup>2</sup> This publication cites and refers to methods from an earlier publication [Feng et al., 2022], partly using the same study population. That earlier publication has been retracted with the following statement [from BMC Public Health. 2022; 22: 2044]: “The Editor has retracted this article. After publication, concerns were raised regarding the data analysis and conclusions in the paper. The authors have provided raw data, and post-publication review found inconsistencies in methodology and major misinterpretation of the primary result. None of the authors agree to this retraction.” Although Feng et al. (2022) was included in the current systematic review, the link between the two publications suggests that caution is warranted in interpreting any results.

## Assessment of quality of newly identified original human studies

The quality of included studies was assessed using the OHAT risk of bias tool <sup>[5]</sup> as summarized in Table 4. Fifty-one percent of studies (n=45) were of high quality, compared to forty-seven percent that were of acceptable quality (n=42). Detailed assessment for individual studies is included in Section 3 of the Supplementary Material.

Table 4: Quality assessment for included human studies using OHAT risk of bias tool

Study	Selection bias			Confounding bias	Performance bias		Attrition/exclusion bias	Detection bias		Selective reporting bias	Other sources of bias	Overall quality of evidence (Score)
	Was administered dose or exposure level adequately randomized?	Was allocation to study groups adequately concealed?	Were the comparison groups appropriate?	Did the study design or analysis account for important confounding and modifying variables?	Were experimental conditions identical across study groups?	Were the research personnel and human subjects blinded to the study group during the study?	Were outcome data complete without attrition or exclusion from analysis?	Can we be confident in the exposure characterization?	Can we be confident in the outcome assessment?	Were all measured outcomes reported?	Other potential threats to internal validity

**Assessment criteria**

Key criterion

Level of bias

## Newly identified reviews of human studies

While a total of five published original reviews of the fluoride scientific literature passed the three-question screening criteria for further consideration, none were ultimately of sufficient methodological rigor or comprehensive to be considered as updates of the CADTH or NTP reviews. A brief summary of the assessment and the authors' reported conclusions are shown in Table 5.

Table 5: Summary of eligible reviews of human evidence<sup>27</sup>

<b>Reference (Study Design)</b>	<b>Comprehensiveness</b>	<b>Methodological Rigor</b>	<b>Summary of Author-reported conclusions</b>
<i>Grandjean 2019</i> <sup>[79]</sup> (Literature Review)	<p><b>Time Period Covered by Search</b></p> <ul style="list-style-type: none"> <li>• Restricted to most recent 10 years</li> </ul> <p><b>Sources Searched</b></p> <ul style="list-style-type: none"> <li>• Electronic databases (PubMed)</li> <li>• Grey literature (Yes)</li> <li>• Reference list of articles (Yes)</li> </ul> <p><b>Number of References Included</b></p> <ul style="list-style-type: none"> <li>• N= 14 cross-sectional studies</li> <li>• N= 5 prospective studies</li> <li>• N= 2 retrospective studies</li> </ul>	<p><b>Was screening conducted by two independent reviewers?</b></p> <ul style="list-style-type: none"> <li>• NR</li> </ul> <p><b>Was data abstraction conducted by two independent investigators?</b></p> <ul style="list-style-type: none"> <li>• NR</li> </ul> <p><b>Was quality assessment conducted by two independent investigators?</b></p> <ul style="list-style-type: none"> <li>• NR</li> </ul>	<p>The recent epidemiological results support the notion that elevated fluoride intake during early development can result in IQ deficits that may be considerable. Recognition of neurotoxic risks is necessary when determining the safety of fluoride-contaminated drinking water and fluoride uses for preventive dentistry purposes.</p>
<i>Saeed 2019</i> <sup>[80]</sup> (Literature Review)	<p><b>Time Period Covered by Search</b></p> <ul style="list-style-type: none"> <li>• 1989 to 2019</li> </ul> <p><b>Sources Searched</b></p> <ul style="list-style-type: none"> <li>• Electronic databases (PubMed, Environmental Health Perspectives, MEDLINE, Google</li> </ul>	<p><b>Was screening conducted by two independent reviewers?</b></p> <ul style="list-style-type: none"> <li>• NR</li> </ul> <p><b>Was data abstraction conducted by two independent investigators?</b></p>	<p>The significant downsides of fluoride outweigh its benefits for dental problems across many endemic areas of the world. The findings in past literature studies are alarming and the seriousness of this debate urges expediting policymaking and awareness campaigns for public safety.</p>

<sup>27</sup> Information and data in this table was taken directly from the original publications

Reference (Study Design)	Comprehensiveness	Methodological Rigor	Summary of Author-reported conclusions

The studies conducted and the organizational reports published after the 2010 Health Canada fluoride document and until May 10, 2017 corroborate these findings.</li> </ul>

NR = Not Reported; NA = Not Applicable

## Animal evidence

The search strategy resulted in retrieval of 2,119 non-duplicate records from bibliographic databases. Upon excluding 1,628 irrelevant studies during title and abstract screening, there were 446 studies left for full-text examination. One hundred and ninety-nine original animal studies were finally retained for data abstraction and detailed analysis. A detailed PRISMA flow diagram <sup>[14]</sup> showing the selection process for human studies is shown in Figure 3. A summary of studies excluded at levels 1 and 2, grouped by reason of exclusion is shown in Table 6, and detailed in full in Section 4 of the Supplementary Material.

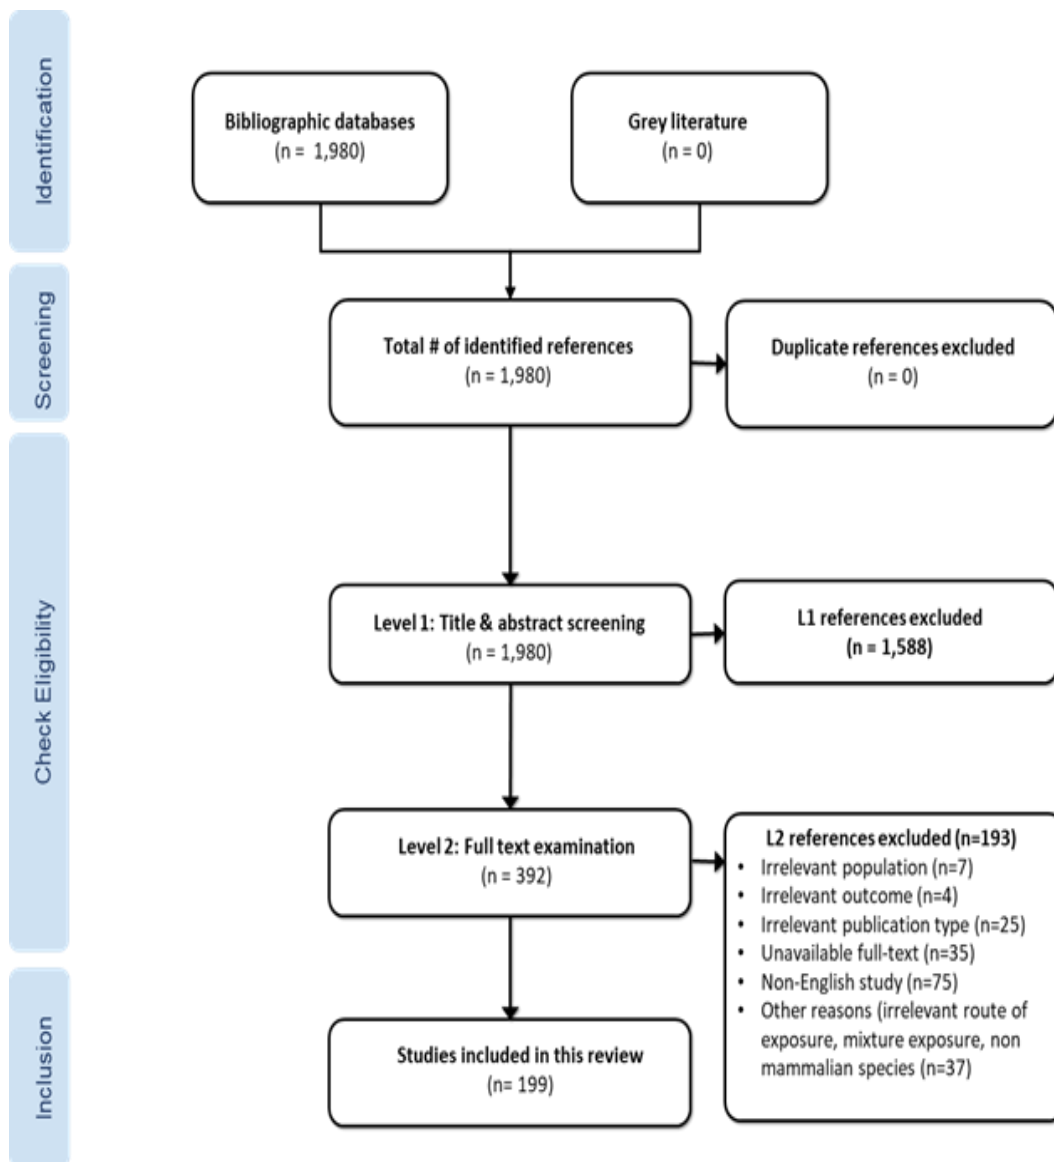

Figure 3: PRISMA flow diagram for animal studies

Table 6: Animal studies excluded at levels 1 and 2 by exclusion reason/group

Level	Exclusion group	Reason for exclusion	# of studies	
L1	Ineligible	One or more exclusion criteria	1,628	
L2	Language	Non-English publication	76	
	Duplicate	Duplicates	7	
	Unavailable full-text	No pdf available	37	
	Irrelevant outcome	Outcome out of scope	8	
	Irrelevant population	Human subjects		5
		In vitro models (e.g., mammalian cells/ tissues, bacterial cells, plant cells)		3
	Irrelevant publication type	Non-systematic reviews		11
		Commentary/communication/editorial/letter/ conference abstract/poster/presentation		16
	Other exclusion reasons	Including route of exposure other than drinking water, mixture exposure, non-mammalian species		43

### Data abstraction and prioritization of animal Studies

After screening, based on title, abstract and full-text reading, of 2,119 articles, 199 non-human mammalian studies were found eligible for further consideration. Table 7 shows the list of animal studies by outcome. This data covers most of the primary outcomes with the largest body of evidence on neurotoxicity and developmental/ reproductive toxicity. To handle the large volume of animal data, following similar approaches by US NTP and EU REACH, a tiered approach was implemented where only a subset (tier-1) of eligible studies would be considered for complete data abstraction, and the data from remaining studies (tier 2 and below) were generally not extracted but used as supporting information.

This criteria were designed to give preference to studies with exposure doses relevant to humans ( $\leq 20$  ppm), studies that provide understanding of the dose-response relationship (more than single dose), and those that were not included in another authoritative review, as well as guideline studies; lower tier studies include those where the primary focus was protection against or interaction with fluoride toxicity or mechanism of action (e.g. oxidative stress), or were single exposure dose studies.

Table 7: List of animal studies retained for qualitative analysis, by endpoints

## Characteristics of included animal studies

A total of 35 tier-1 and 55 tier-2 studies were included in examining (and updating) the evidence of fluoride induced adverse health effects in experimental animals. Information on all primary endpoints was extracted from each study, and only tier-1 studies were assessed for study quality. Across all endpoints examined, excluding neurological outcomes, the largest amount of data was on reproductive outcomes. A comprehensive summary of important study characteristics of all tier 1 and tier 2 studies included in the current review is provided in Table 8 and Table 9.

Table 8: Study characteristics and results of included tier-1 animal studies

Study design	Exposure <sup>28</sup> & Outcomes	Results	Authors' conclusion	Quality
<b>Reproductive toxicity</b>				
<b>Cao 2016</b> <sup>[109]</sup>				
<b>Oral (drinking water), subchronic mice study</b>	Exposure	D-R relationship: <b>increase in all reproductive endpoints assessed with increase in NaF concentration</b>	"NaF did have toxic effects on male reproductive system, which reduced the testosterone content and sperm number, and increased the abnormality ratio of sperm and sperm head, supported by the damages of the testicular structure, as a consequence of depressed HSF2 level, which resulted in the downregulation of Ssty2 and Sly mRNA and protein."	1

<sup>28</sup> When not reported by authors, exposure concentrations (mg/L or ppm fluoride) are converted into doses (indicated with an asterisk '\*') using the following default conversion factors, as recommended by Health Canada (1994) 324. Canada, H., *Human health risk assessment for priority substances*. Ottawa, ON: Ministry of Health. 1994, Health Canada.: 1 ppm or mg/L chemical in water equals to 0.14 mg/kg bw/day in rats or 0.20 mg/kg bw/day in mice.

Study design	Exposure <sup>28</sup> & Outcomes	Results	Authors' conclusion	Quality
	genes (qPCR) and proteins (ELISA)	the lumen; overall histological examination indicated aggravated testicular tissue damage in all treatment groups. - Testosterone levels in serum and testis: both levels were significantly decreased in higher treatment groups (50 and 100 mg/L). - Gene and Protein expression: the mRNA expressions of spermiogenesis specific genes (Ssty2, Sly, HSF2) corresponding protein levels were changed markedly in higher treatment groups (50 and 100 mg/L).		
<b>Chaithra 2019</b> <sup>[114]</sup>				
<b>Oral (gavage), subchronic rat study</b> • Adult Wistar rats, males only • 5 animals/ group, 4 groups	Exposure • Sodium fluoride (NaF) • 0, 0.45, 2.26, 4.5 mg/kg bw/day • Vehicle - de-ionized water • 52 days of exposure Outcomes assessed • <b>Reproductive toxicity</b> • Specific outcomes: - Sperm count, motility, and abnormality - Activity of testicular 3β-hydroxysteroid dehydrogenase (3β-HSDH) - Testosterone concentration in serum - Histology of testis (germ cell count in spermatogenesis) - Activity of oxidative stress markers (superoxide dismutase SOD, catalase CAT and malondialdehyde MDA)	D-R relationship: <b>increase in several reproductive parameters with increase in dose</b> • Results: - Body or tissues weights: significant decrease in testis, epididymis and seminal vesicle tissue weight (relative) of 5 and 10 mg/kg bw groups; and decrease in % body weight gain in all treated animals - Sperm count: significant reduction in sperm count and increase in abnormal spermatozoa of all treated animals - Testosterone levels: serum testosterone levels were significantly reduced with increase in NaF dose; 3β-HSDH levels were significantly reduced in 5 and 10 mg/kg bw/day groups. - Histology: distorted & shrunken seminiferous tubules and loss of spermatogonial cells with increased severity (complete loss) in highest dosed animals. A significant dose-dependent decrease in counts of various germ cell types of spermatogenesis. - Antioxidant enzymes: significant dose-dependent reduction in testicular SOD and CAT enzymatic levels; significant increase in testicular MDA levels of 5 and 10 mg/kg bw/day groups	“Exposure to F-contaminated groundwater affects spermatozoa, steroidogenesis, and spermatogenesis by inducing oxidative stress. The alterations induced by NaF on the male reproductive system are dose-dependent and increased concentration of NaF causes severe damage to the system. Further, the study reveals that F-induced alterations in reproductive system are reversible.”	2

detachment. There was a non-significant dose-dependent increase in percentage of injured tubules

**Kobayashi 2009** <sup>[174]</sup>

**Oral (drinking water) subchronic rat study**

- Weanling Wistar rats, males only
- 6 animals/ group, 3 groups

Exposure

- Sodium fluoride (NaF)
  - **0, 0.3, 3 mg/kg bw/day\*** (0, 5, 50 ppm NaF)
  - Vehicle – deionized water
  - 60 days of exposure
- Outcomes assessed

• **Renal or Kidney toxicity**

- Specific outcomes:
  - Renal histopathology
  - Proteomics

D-R relationship: **50 ppm F dose induced marked histological changes in kidneys**

• Results:

- Renal histopathology: No marked abnormal changes were seen kidneys of controls or 5 ppm group rats (except mild vascular congestion in 5 ppm rats). Kidneys of 50 ppm group rats had markedly increased blood vessels, larger glomerular & medullar capillaries engorged with erythrocytes.
- Renal proteomic changes: protein levels related to detoxification, metabolism and endoplasmic reticulum were significantly changed in treated rats, especially in 50 ppm group. Between control vs 50 ppm F, and control vs 5 ppm F groups, 12 and 6 differentially expressed proteins were detected, respectively. Six proteins, mainly related with metabolism, detoxification and housekeeping, were successfully identified. At the high F group, pyruvate carboxylase, a protein involved in the formation of oxaloacetate was found to be downregulated, while enoyl coenzyme A hydratase, involved in fatty acids oxidation, was found to be upregulated.”

In summary, the histological analysis revealed no damage in kidneys induced by F, except for a vascular congestion in the high-dose group. The differentially (down-regulated) expressed kidney proteins in F dose groups belong to 3 main functional categories i.e., detoxification-related proteins, metabolism-related proteins and miscellaneous, including endoplasmic reticulum proteins.

associated with chemical exposure.”

### Neurotoxicity

Nadei 2019 <sup>[215]</sup>

**Oral (drinking water) chronic rat study**

- PND42 Wistar rats, males only
- 10 animals/ group, 4 groups

Exposure

- Sodium fluoride (NaF)
- **0, 0.7, 2.8, 7 mg/kg bw/day\*** (0, 5, 20, 50 ppm F)

• Vehicle – water

• 12 months of exposure  
Outcomes assessed

• **Neurotoxicity**

• Specific outcomes:

- Short-term and long-term memory (using novel object recognition (NOR) test)
- Spatial learning and memory (using Morris water maze test)
- Expression of Calpain proteins in hippocampus

D-R relationship: **all three doses caused an impairment in the processes of spatial learning and formation of long-term memory**

• Results:

- Novel object recognition: in 1 hour session, a significant decline in DI (discrimination index), an index of recognition memory, in rats exposed to 50 ppm fluoride was noted; the decline noted in 5 and 20 ppm groups was not statistically significant. In 24 hours after training, the rats from all three fluoride groups were not able to discriminate between new and familiar object, with DI being a few times less than that of control rats for animals given 20 and 50 ppm fluoride.
- Morris water maze test: Following everyday training, escape latency substantially decreased in all groups of animals. However, starting from day 3, efficiency for spatial learning was significantly lower for rats in 5 and 50 ppm whereas inconsistent in 20 ppm group. In spatial probe test (day 6), the rats from 20 ppm fluoride group had lesser number of visits to target quadrant and, accordingly, spent less time and swam shorter distance within this quadrant. The distance traveled in target zone by the animals exposed to 50 ppm fluoride was also shorter. No statistical difference in these parameters was revealed for rats from 5 ppm group.

“The results of our work have shown that long-term consumption of excessive F<sup>-</sup> doses exerts pronounced negative impact on cognitive capacities of rats and on their hippocampal cells. Although the formation of short-term memory was sensitive to 50 ppm F<sup>-</sup> only, all three F<sup>-</sup> doses induced the deficit of long-term memory.” And, “altered expression of signaling molecules of calpain-1 cascade at background of stable activity of calpain-2 and its effectors, observed in rat hippocampus after long-term F<sup>-</sup> intoxication, suggests the disruption of link between early and late LTP phases, i.e., between induction and consolidation of memory, leading to decline in cognitive capacities of animals.”

1

Study design	Exposure <sup>28</sup> & Outcomes	Results	Authors' conclusion	Quality
		- A dose-dependent decline of calpain-1 content in cytoplasm of hippocampus, but significant increase of its expression in membrane fractions in comparison to control		
<b>Teng 2018</b> <sup>[266]</sup>				
<b>Oral (drinking water) chronic rat study</b>	<p>Exposure</p> <ul style="list-style-type: none"> <li>• Sodium fluoride (NaF)</li> <li>• <b>0, 0.9, 1.9, 3.8 mg/kg bw/day*</b> (0, 15, 30, 60 mg/L NaF)</li> <li>• Vehicle – water</li> <li>• 18 months of exposure</li> </ul> <p>Outcomes assessed</p> <ul style="list-style-type: none"> <li>• <b>Neurotoxicity</b></li> <li>• Specific outcomes: <ul style="list-style-type: none"> <li>- Ca<sup>2+</sup> concentration in rats' hippocampus</li> <li>- CaMKII<math>\alpha</math> expression</li> <li>- c-fos expression</li> <li>- Histology and Immunochemistry of brain</li> </ul> </li> </ul>	<p><b>D-R relationship:</b></p> <ul style="list-style-type: none"> <li>• Results: <ul style="list-style-type: none"> <li>- <b>[Ca<sup>2+</sup>] increased in all treatment groups</b>, with significant increases noted in the 30 and 60 mg/L groups</li> <li>- CaMKII<math>\alpha</math> increased significantly in the 30 and 60 mg/L groups</li> <li>- c-fos increased significantly in the 30 and 60 mg/L groups</li> </ul> </li> </ul>	<p>"In conclusion, our data showed fluorosis could lead to the enhancement of [Ca<sup>2+</sup>] and the expression level of CaMKII<math>\alpha</math> and c-fos in the rat hippocampal CA3 region. The results support the idea that fluorosis can exert neurotoxic effects by changing the [Ca<sup>2+</sup>] in nerve cells. Calcium overload in the hippocampus may be the initiating factor of neuronal apoptosis induced by fluoride. We deduce that Ca<sup>2+</sup>/CaMKII<math>\alpha</math>/c-fos channel signal may be a molecular mechanism of central nervous system damage induced by chronic fluoride intoxication"</p>	1

---	--	---	--

Study Design	Exposure & Outcomes	Results	Authors' Conclusion
--------------	---------------------	---------	---------------------

- Serum concentrations of ALP and OCN (biomarkers of bone differentiation) were increased in middle and high F groups
- Wnt3a (ligand of Wnt/b-catenin signaling pathway) was significantly up-regulated in the 50 and 100 mg/L F- groups. F gradually increased the protein expression of Gsk3b phosphorylation, b-catenin and its downstream target gene Runx2, which was accompanied by translocation of b-catenin into the nucleus induced by fluoride. F exposure was correlated with increased Wnt3a, b-catenin, the ratio of p-Gsk3b (Ser9) to Gsk3b and Runx2 protein levels

<ul style="list-style-type: none"> <li>• 20 animals/sex/group, 4 groups (male offspring = 5/group)</li> </ul>	<ul style="list-style-type: none"> <li>• <b>Reproductive toxicity</b></li> <li>• Specific outcomes:               <ul style="list-style-type: none"> <li>- Testicular Histopathology</li> <li>- Testicular ultrastructure</li> <li>- Germ cell apoptosis</li> <li>- Oxidative stress markers in testis (MDA and SOD activity)</li> </ul> </li> </ul>	<p>of elongated spermatids in the severely damaged seminiferous tubules, indicative of impaired spermatogenesis and loss of germ cells in 50 and 100 mg/L groups;</p> <ul style="list-style-type: none"> <li>- Testicular ultrastructure: many spermatogonia and spermatocytes displayed the characteristic features of apoptosis, including condensation and margination of nuclear chromatin in 50 and 100 mg/L groups</li> <li>- Germ cell apoptosis: TUNEL-positive cells were notably increased in testes of 50 and 100 mg/L NaF; apoptotic cells accounted for degenerating spermatogonia and spermatocytes</li> <li>- Oxidative stress markers: marked increase of MDA levels in the 50 and 100 mg/L groups; significant reduction in enzymatic activities of SOD in all treated groups</li> </ul>	<p>spermatogenesis and accompanying decrease in germ cell count. Furthermore, the present study has also provided important new insights into the roles of ER stress and inflammation in the aggravation of testicular damage.”.</p>

## Assessment of quality of the identified animal studies (Tier-1)

The quality of included studies was assessed using the OHAT risk of bias tool <sup>[5]</sup> as summarized in Table 10. Fifty-six percent of studies (n=20) were of high quality (Q=1), compared to 39% percent that were of acceptable quality (n=14).

Table 10: Quality assessment for animal studies (Tier-1) using OHAT risk of bias tool

Study	Was administered dose or exposure level adequately randomized?	Was allocation to study groups adequately concealed?	Were experimental conditions identical across study groups?	Were the research personnel and human subjects blinded to the study group during the study?	Were outcome data complete without attrition or exclusion from analysis?	Can we be confident in the exposure characterization?	Can we be confident in the outcome assessment?	Were all measured outcomes reported?	Were there any other potential threats to internal validity? ## VII. Literature review summary

### Summary of evolving human evidence

Out of a total of 39 endpoints reported in the RSI review, the RSI literature search identified new human evidence relating to 16 endpoints, which were not reported in either NHMRC<sup>[9, 10]</sup> or CADTH<sup>[2, 3]</sup> reports. CADTH had initially reported on 23 endpoints, for which the RSI review updated the evidence on 13 of those endpoints and found no new evidence on the remaining 10 endpoints. This section describes the evolving evidence reported in NHMRC 2016, CADTH 2019, and the current updated review of the literature. A summary is provided for all endpoints in Table 11. Where no earlier evidence was reported, the CADTH 2019 conclusion was described as 'N/A'. While no limit was used to restrict studies based on fluoride exposure levels as an exclusion criterion for the literature review, synthesis of evidence was predominantly based on studies generally relevant to the Canadian context. Although these studies may involve fluoride water concentration higher than those in Canadian drinking water supplies, they are relevant to the evaluation of causality and exposure-response assessment. Some studies reported results based on serum/urinary fluoride levels (detailed in Section 3 of the Supplementary Material). Where available, fluoride levels in drinking water were listed in the following section for the purpose of comparison across studies.

### All-cause mortality

NHMRC 2016<sup>[9, 10]</sup> identified one major study with acceptable quality that reported a small decrease in all-cause mortality incidence in association with CWF. No further evidence was identified by CADTH 2019<sup>[2]</sup> or RSI literature search in relation to all-cause mortality.

*RSI evidence synthesis:* In the absence of new studies, the CADTH summary of evidence remains unchanged: Insufficient evidence for an association between water fluoridation at the current Canadian levels and all-cause mortality.

## **Bone health**

### **Bone, cancer**

NHMRC [9, 10] identified three studies of acceptable quality and three of low quality, where all except one of low quality concluded no association between water fluoridation and bone cancer. NHMRC also identified two systematic reviews where one reported a positive association only in males, and the other reported no clear association. CADTH 2019 [2] identified two further studies of acceptable quality and reported that the evidence up to that date was largely in support of no association between fluoride and bone cancer. The RSI literature search identified 1 case control study [33] and 2 ecological studies [35, 43] of high/acceptable quality that were conducted in South Korea [35], and the US [33, 43]. Two of these studies concluded the absence of association between bone cancer and water fluoridation at a fluoride exposure range between 0.04-0.8 ppm [33, 43]. The third study [35] that concluded the absence of association did not report a water fluoride exposure level.

*RSI evidence synthesis:* Based on the available literature to date, there is consistent evidence of no association between bone cancer and fluoride exposures relevant to current Canadian drinking water levels.

### **Bone, density and quality**

NHMRC 2016 [9, 10] identified one systematic review and one study of low quality, which concluded the absence of association between bone quality or osteoporosis (low mineral bone density) and exposure to fluoride. No further evidence was identified by CADTH 2019 [2]. The RSI literature search identified 5 new studies including 4 studies of high quality [21, 32, 35, 39] and a fifth study with acceptable quality [65]. One cohort study from Sweden [21] and 2 cross-sectional studies from China [39] and Ethiopia [32] concluded a positive association between bone quality disruption and fluoride in drinking water ( $\leq 1$  ppm) [21] or ground water (6.8 ppm) [32]. The Chinese study [39] did not report on the examined fluoride exposure level. Alternatively, 2 studies reported no association between fluoride exposure/intake and bone quality disruption. One ecological study was conducted in South Korea [35] on residents from all ages (no water fluoride level reported). Another US cohort study [65] was conducted on

adolescents (17 years of age) and reported no association between bone quality disruption and life-long fluoride intake from all sources (0.7-0.9 ppm) [65].

*RSI evidence synthesis:* Based on the available literature to date, there is inconsistent evidence for the association of bone quality and fluoride exposures relevant to current Canadian drinking water levels.

### **Bone, hip fracture**

NHMRC 2016 [9, 10] reported two systematic reviews and two studies of acceptable quality, which showed no clear association between fluoride and hip fractures. The later review by CADTH 2019 [2] identified one additional study of acceptable quality and concluded that evidence was consistent for no association with fluoride exposure. The RSI literature search identified 1 ecological study [35] of high quality that was conducted in South Korea and concluded the absence of an association between fluoride exposure and the risk of hip fracture.

*RSI evidence synthesis:* Based on the available literature to date, there is consistent evidence of no association between hip fracture and fluoride exposures relevant to current Canadian drinking water levels.

### **Bone, musculoskeletal pain**

NHMRC 2016 [9, 10] identified two studies of low quality, which reported a positive association between musculoskeletal pain and higher fluoride levels (not applicable to the Canadian context). No further evidence was identified by CADTH 2019 [2] or in the current updated literature review in relation to musculoskeletal pain.

*RSI evidence synthesis:* In the absence of new studies, the CADTH summary of evidence remains unchanged: Insufficient evidence for an association between water fluoridation at the current Canadian levels and musculoskeletal pain.

## **Cancer, total incidence and mortality**

The earlier review by NHMRC 2016 <sup>[9, 10]</sup> reported conflicting evidence for the association of cancer incidence and mortality based on examination of two systematic reviews and three individual studies of acceptable quality. CADTH 2019 <sup>[2]</sup> identified an additional study of acceptable quality that reported an inverse association and concluded that there was consistent evidence of no association. The RSI literature search did not identify any new evidence relating to cancer incidence and mortality.

*RSI evidence synthesis:* In the absence of new studies, the CADTH summary of evidence remains unchanged: Consistent evidence for no association between water fluoridation at the current Canadian levels and the overall incidence of cancer or cancer-related mortality.

## **Cognition**

Cognition, ADHD

There were no earlier studies identified in NHMRC 2016 <sup>[9, 10]</sup> or CADTH 2019a <sup>[3]</sup> that reported on the association of fluoride with ADHD. The RSI literature search identified two studies of high quality which examined the association between fluoride exposure and ADHD in youth <sup>[52]</sup> and in children due to maternal exposure to fluoride during pregnancy <sup>[58]</sup>. The first one <sup>[52]</sup> was a cross-sectional study conducted on Canadian youth 6-17 years old from the Canadian Health Measures Survey (Cycles 2 and 3). The study reported a significantly positive association between tap water fluoride (mean of 0.04 mg/L in non-fluoridated regions to 0.49 mg/L in fluoridated regions) and the risk of ADHD including symptoms of hyperactivity and inattention, especially among adolescents. The second study <sup>[58]</sup> was a cohort study conducted in Mexico, which enlisted 213 mother-child pairs as part of the ELEMENT study. This study reported an association between higher maternal fluoride levels (measured during pregnancy, mean MUFcr was 0.85 mg/L (SD=0.33)) and “more behavioral symptoms of inattention, but not hyperactivity or impulse control” measured in the children at 6-12 years old. In the study, water fluoride levels of 0.15-1.38 ppm were extrapolated from an earlier study on the ELEMENT cohort in 2017 <sup>[71]</sup>.

*RSI evidence synthesis:* Based on the available literature to date, there is insufficient evidence to evaluate an association of ADHD and fluoride exposures relevant to current Canadian drinking water levels.

### **Cognition, dementia**

There were no earlier studies identified in NHMRC 2016 [9, 10] or CADTH 2019a [3] that reported on the association of fluoride with dementia. The RSI literature search identified one large, high quality cohort study [37] that was conducted in Scotland and included all people born in 1921 who were at school in Scotland in June 1932, and took part in a comprehensive national intelligence test at a mean age of 11 years (Scottish Mental Survey 1932, SMS1932). The study reported a positive association between the risk of dementia and higher fluoride levels in men and women who consumed water with low fluoride levels (0.05 ppm).

*RSI evidence synthesis:* Based on the available literature to date, there is insufficient evidence to evaluate an association of dementia and fluoride exposures relevant to current Canadian drinking water levels.

### **Cognition, Down syndrome**

NHMRC 2016 [9, 10] reported on two systematic reviews which did not show a clear association between fluoride and Down syndrome, compared to another study with a large population size and acceptable quality that showed no such association. CADTH 2019a [3] identified an additional, large-size observational study with acceptable quality that reported no association of fluoride exposure and Down syndrome. The RSI literature search did not identify any new evidence relating to Down syndrome.

*RSI evidence synthesis:* In the absence of new studies, the CADTH summary of evidence remains unchanged: Limited evidence for no association between water fluoridation at the current Canadian levels and Down syndrome.

### **Cognition, IQ**

Based on one systematic review and eleven studies (1 high, 2 acceptable, and 8 low quality), the NHMRC 2016 [9, 10] reported mixed findings regarding the association of fluoride exposure

with lower IQ scores in children. A subsequent report by CADTH 2019a <sup>[3]</sup> identified a Canadian cohort study <sup>[326]</sup> that used data from the MIREC birth cohort, which was conducted on mother-child pairs from six major Canadian cities. The study reported a positive association between maternal exposure to fluoride and reduction of IQ levels in children 3-4 years old. Despite describing the evidence as weak based on this single cohort study, CADTH 2019a <sup>[3]</sup> suggested that results should be part of the efforts to further explore the possible association of fluoride exposure and neurological development in children. In a 2020 update to their 2019 review of neurological and cognitive effects, CADTH <sup>[327]</sup> identified two additional studies of low quality in relation to IQ, and concluded there was insufficient evidence for an association between IQ levels and “fluoride exposure at the Canadian water fluoride levels (optimum at 0.7 mg/L)”.

A 2020 draft report<sup>29</sup> <sup>[328]</sup> by the US National Toxicology Program (NTP) concluded that exposure to fluoride “*is presumed to be a cognitive neurodevelopmental hazard*” in children, with only limited evidence in support of cognitive effects in adults. This statement was modified in 2022 <sup>[420]</sup> in response to another NASEM review: “This review finds, with moderate confidence, that higher fluoride exposure (e.g., represented by populations whose total fluoride exposure approximates or exceeds the World Health Organization Guidelines for Drinking-water Quality of 1.5 mg/L of fluoride) is consistently associated with lower IQ in children. More studies are needed to fully understand the potential for lower fluoride exposure to affect children’s IQ.” According to NTP, for effects on children’s IQ at exposure levels below 1.5 mg/L, the supporting studies provided less consistent results and were mostly at higher risk of bias. “”

The RSI literature search identified a total of 22 studies including 18 studies (12 high <sup>[40, 41, 59, 69, 71, 405, 409, 413, 415-416, 418-419]</sup> and 6 acceptable quality <sup>[64, 70, 76, 401, 414, 417]</sup>) that reported a positive association between fluoride exposure and reduced IQ scores and school performance in children. Studies reporting positive association include the Till and Colleagues <sup>[40]</sup> study, using MIREC birth cohort data, which reported that an increment of 0.5 mg/L in

---

<sup>29</sup> NTP disclaimer: “This DRAFT Monograph is distributed solely for the purpose of pre-dissemination peer review under the applicable information quality guidelines. It has not been formally disseminated by NTP. It does not represent and should not be construed to represent any NTP determination or policy. The September 6, 2019 draft monograph was peer reviewed by a committee convened by the National Academy of Sciences, Engineering, and Medicine (NASEM). This current draft incorporates changes in response to that review and is being submitted to the same NASEM committee for an additional round of peer review.”

water fluoride concentration corresponded to a 9.3- and a 6.2-point reduction in performance IQ in formula-fed and breastfed children, respectively. Such an association remained significant upon controlling for fetal fluoride exposure.

Results from a recent study <sup>[418]</sup> that used data from the Mexican Cohort ELEMENT suggests that maternal urinary fluoride exposure may affect visual-spatial and perceptual cognitive domains more so than verbal. The study reported a drop of 2 points in IQ scores for each 0.5 mg/L increase in maternal urinary fluoride. Another recent and high-quality analysis of critical time windows of exposure using the Canadian MIREC cohort, reported an association between children's performance IQ and fluoride exposure during the perinatal period and into early childhood. Results suggest that prenatal exposure may be more critical for effects in boys but infancy (over the first year) as the more critical exposure window for girls <sup>[409]</sup>. A third study <sup>[419]</sup> examined prenatal fluoride exposure in a small mother-child birth cohort in Spain: Results in boys suggest improved scores in cognitive domains with maternal urinary concentrations. Another study <sup>[69]</sup> reported that each increment of 0.5 mg/L in water fluoride corresponds to a 40% reduction in the odds of having excellent IQ in those exposed to low fluoride levels (0.20-1.40 mg/L). In 2020, Wang and Colleagues <sup>[41]</sup> reported a significant IQ score reduction for each 1 mg/L increase in water fluoride concentration [ $\beta$ : -1.59 (-2.61, -0.57),  $p=0.002$ ].

Another high-quality study <sup>[59]</sup> reported an association with reduced IQ scores only in children carrying the dopamine receptor-2 (DRD2) Taq 1A- TT genotype, with no similar association with the other DRD2 Taq 1A genotypes. In a high-quality study <sup>[71]</sup> from Mexico (using data from the ELEMENT cohort), the authors reported a positive association of maternal exposure to fluoride during pregnancy with lower GCI (IQ) scores in children at approximately 4 years old, and with lower Full-Scale IQ scores at 6–12 years old. And finally, a cross-sectional study conducted by Kousik and Colleagues in 2016 <sup>[76]</sup> reported a positive and significant correlation between exposure dose and IQ ( $r = -0.343$ ,  $p < 0.01$ ).

These studies reported a reduction of IQ scores in association with water fluoride concentrations of 0.01-2.07 ppm <sup>[64]</sup>, 0.1–1.6 ppm <sup>[414]</sup>, 0.1–15.8 ppm <sup>[405]</sup>, 0.15-1.38 ppm <sup>[71]</sup>, 0.20–2.49 ppm <sup>[59]</sup>, 0.20–3.90 ppm <sup>[413]</sup>, 0.58 ppm <sup>[40]</sup>, >1.0 ppm <sup>[417]</sup>, 1.39 ppm <sup>[41]</sup>, >1.5 ppm <sup>[70]</sup>, 1.53–2.84 ppm <sup>[416]</sup>, 2.0 ppm <sup>[69]</sup>, 2.11 ppm <sup>[76]</sup>, and 2–5 ppm <sup>[401]</sup>. Three studies with

acceptable quality reported no effect of fluoride on children's IQ at fluoride exposures of 0.3-3.0 ppm [75], 1.22 ppm ±1.09 [54], or 2.04 ppm [398].

*RSI evidence synthesis:* Based on the available literature to date, the accumulating body of evidence suggests a positive association of reduced IQ scores for children and fluoride exposures relevant to current Canadian drinking water levels.

### **Cognition, memory loss**

There were no earlier studies identified in NHMRC 2016 [9, 10] or CADTH 2019a [3] that reported on the association of fluoride with memory loss. The RSI literature search identified only one case-control study [70] with acceptable quality that was conducted in India and examined men and women with dental and skeletal fluorosis. The study reported a positive association between fluoride exposure (>1.5 ppm) and several biomarkers (decreased activity of the membrane bound enzymes, AChE and ATPase). These results indicate defects in signaling and energy metabolism, and can predict potential memory loss (unmeasured in the study) in fluorosis patients.

*RSI evidence synthesis:* Based on the available literature to date, there is insufficient evidence to evaluate an association of water fluoride and memory loss.

### **Cognition, trouble working**

There were no earlier studies identified in NHMRC 2016 [9, 10] or CADTH 2019a [3] that reported on the association of fluoride with trouble working. The RSI literature search identified a large cross-sectional study [75] with acceptable quality that was conducted using data on >500,000 US adolescents and adults from the National Health and Nutrition Examination Survey III (NHANES III). The study reported no association between exposure to water fluoride (0.3-3 ppm) and trouble working.

*RSI evidence synthesis:* Based on the available literature to date, there is insufficient evidence to evaluate an association of trouble working and fluoride exposures relevant to current Canadian drinking water levels.

## **Cardiovascular Diseases (CVD)**

A number of studies examining individual cardiovascular endpoints were reported in earlier reviews [2, 9] as well as by the current RSI review. Whereas the evidence for each individual endpoint is supported by few studies, and given the fact that these endpoints are closely interrelated, the evolving evidence merits further investigations to properly assess the association of fluoride exposure with cardiovascular diseases.

### **CVD, atherosclerosis**

Based on a single study with low quality, NHMRC 2016 [9, 10] reported a significantly higher risk of carotid artery atherosclerosis in adults in areas with high fluoride levels (>1.2 ppm). No further studies were identified by CADTH 2019 [2]. The RSI literature review identified 3 additional studies that examined the association of fluoride with cardiovascular disease biomarkers. A cross-sectional study [27] with acceptable quality in Ukraine reported that children in the fluorosis area (>1.5 ppm) showed higher blood TBARS levels, while the acyl hydroperoxide levels were non-significantly increased in comparison with healthy children living in the non-fluorosis area. Another cross-sectional study with high quality [45] that was conducted in 2015 on 5-12 years old Mexican school children. The study reported significant association of fluoride exposure (0.3 ppm) with alterations in some cardiovascular disease biomarkers, suggesting fluoride exposure may be atherogenic and may increase the likelihood of cardiovascular diseases later in life. A third study of case-control design with acceptable quality [70] was conducted on patients with dental and skeletal fluorosis in India. The study reported variable associations of fluoride (>1.5 ppm) with different cardiovascular disease biomarkers, which support the chances of cardiovascular-related complications in fluorosis patients.

*RSI evidence synthesis:* Based on the available literature to date, there is limited evidence for an association of atherosclerosis and fluoride exposures relevant to current Canadian drinking water levels.

### **CVD, hypertension**

Five studies were reported by NHMRC 2016 [9, 10] (n=3) and CADTH 2019 [2] (n=2) provided mixed findings on the association of fluoride with risk of hypertension. All studies were of low quality and were derived from countries with higher fluoride levels compared to those

implemented in Canada. The RSI literature review did not identify any additional studies in relation to this endpoint.

*RSI evidence synthesis:* In the absence of new studies, the CADTH summary of evidence remains unchanged: Insufficient evidence for an association between water fluoridation at the current Canadian levels and hypertension.

## **CVD, myocardial infarction**

There were no earlier studies identified in NHMRC 2016 [9, 10]. With only one study with large population size and low quality that reported no association between fluoride and myocardial infarction, CADTH 2019 [2] concluded there was insufficient evidence for this association. The RSI literature review did not identify any additional studies in relation to myocardial infarction.

*RSI evidence synthesis:* In the absence of new studies, the CADTH summary of evidence remains unchanged: Insufficient evidence for an association between water fluoridation at the current Canadian levels and myocardial infarction.

## **Diabetes mellitus**

As reported by CADTH 2019 [2], there were only two earlier studies with low quality that provided mixed evidence for the association of exposure to fluoride with risk of diabetes mellitus (DM). No earlier studies were identified by NHMRC 2016 [9, 10]. The RSI literature search identified 1 study of high quality that was conducted in India and concluded that the increase in serum Fluoride increases diabetes mellitus and diabetic nephropathy [34]. Serum fluoride levels ranged from  $0.5128 \pm 0.30$  (DM with CKD) to  $0.6318 \pm 0.59$  (DM without CKD).

*RSI evidence synthesis:* Based on the available literature to date, there is insufficient evidence to evaluate an association of diabetes mellitus and fluoride exposures relevant to current Canadian drinking water levels.

## **Eye diseases and conditions**

### **Eye, select diseases**

There were no earlier studies identified in NHMRC 2016 [9, 10] or CADTH 2019 [2] that reported on the association of fluoride with eye diseases. The RSI literature review identified one study [56] of high quality that was conducted on Chinese adults aged  $\geq 40$  years old, with no congenital eye disease or ocular trauma, for examining the association between water fluoride exposure ( $>1.2$  ppm) and seven eye diseases. The study reported significant positive associations with pterygium and arteriosclerotic retinopathy, a significant inverse association with cataracts, and non-significant associations with primary angle closure glaucoma, diabetic retinopathy, age-related macular degeneration, and strabismus.

*RSI evidence synthesis:* Based on the available literature to date, there is insufficient evidence to evaluate an association of any of the examined eye diseases and fluoride exposures relevant to current Canadian drinking water levels.

## **Eye, refractive errors**

An earlier review by CADTH 2019 [2] identified a single low-quality study and concluded that evidence was insufficient for an assessment of this association. There were no earlier studies identified in NHMRC 2016 [9, 10] or RSI literature search in relation to the association of fluoride exposure with the prevalence of refractive errors (myopia, hyperopia, astigmatism) [2].

*RSI evidence synthesis:* In the absence of new studies, the CADTH summary of evidence remains unchanged: Insufficient evidence for an association between water fluoridation at the current Canadian levels and refractory errors.

## **Fluorosis**

### **Fluorosis, dental**

Earlier evidence on the association of fluoride with dental fluorosis was reported by NHMRC 2016 [9, 10] (three systematic reviews) and CADTH 2019 [2] (21 studies: 1 acceptable, 19 low; N= 35,374), which reported consistent findings for an association between fluoride and dental fluorosis. The RSI literature search identified 33 cross-sectional studies, including 15 studies of high quality [19, 22, 25, 57, 62, 72, 77, 402-403, 405-406, 408, 411-413] and 18 studies of acceptable quality [17, 25, 26, 30, 31, 38, 47, 54, 74, 78, 396-397, 399-400, 404, 407, 410, 414] that were not included in earlier reviews. Thirty-two of those studies reported a positive/possible association with dental fluorosis at a

wide range of fluoride concentration in drinking water (both tap and ground). Out of those 32 studies, 14 were of high quality that were conducted in India [62, 72, 399, 400, 404], China [57, 397, 408, 413], Brazil [402, 410, 412], and 1 in each of Canada [403], Egypt [406], Indonesia [414], Iran [77], Malaysia [25], Pakistan [405], Peru [396], Sri Lanka [407], Thailand [411], and USA [19].

The study by Dong et al. (2021) [19] included children and adolescents (age 6 to 19 years), and reported the odds (95%CI) of dental fluorosis (Dean's Fluorosis Index (DFI)  $\geq 1$ ) as 1.48 (1.13, 1.96), 1.92 (1.44, 2.58), and 2.30 (1.75, 3.07) times greater at water fluoride levels of 0.31 – 0.50 mg/L, 0.51 – 0.70 mg/L, and  $>0.70$  mg/L, compared to  $\leq 0.30$  mg/L. Mohd Nor et al. (2021) [25] conducted a study on children (age 9 to 12 years) and reported that compared to those exposed to non-fluoridated water, the odds of dental fluorosis (DFI  $\geq 2$ ) (95% CI) were 5.97 (3.32, 10.72) times greater among children with a lifetime exposure to 0.5 ppm, and 9.12 (5.15, 16.14) times greater among those exposed to 0.7 ppm during the first two years of life, followed by a level of 0.5 ppm.

The study by Zhou and Colleagues [57] included children (age 7 to 13 years) from rural areas with low-to-moderate levels of fluoride and reported that each 1mg/L increase of water fluoride was associated with a 1.47 (1.40, 1.55), 1.85 (1.63, 2.11), 1.68 (1.57, 1.79), and 3.85 (3.01, 4.92) increased odds (95% CI) of total, very mild, mild and moderate dental fluorosis, respectively [57]. The study by Kumar et al. (2018) [62] included adolescents (age 12 to 15 years), and reported a correlation coefficient between water fluoride and dental fluorosis severity of 0.97 (p-value  $<0.05$ ). In the bivariate analysis, the study reported 1.76 (1.31, 2.38) times greater odds (95% CI) of dental fluorosis (any fluorosis, measured using the Modified Dean's Index) among participants exposed to water fluoride levels  $>1.2$  ppm compared to  $\leq 1.2$  ppm.

Verma et al. (2017) [72] included adolescents (age 12 to 17 years) and demonstrated a positive correlation ( $\rho = 0.57$ ) between the Community Fluorosis Index (CFI) and levels of fluoride in drinking water. The study by Sabokseir et al. (2016) [77] included children (age 9 years), and reported the frequency of participants with genuine fluorosis (excludes fluorosis-resembling defects) as 42 (47.7%), 39 (20.6%), and 3 (3.3%) in areas with high, optimal, and low levels of fluoride, respectively. Compared to areas with high levels of fluoride, the odds of genuine dental fluorosis were 70.8% (OR= 0.29, 95% CI: 0.17, 0.51) and 96.3% (OR= 0.04, 95% CI: 0.01, 0.13) less in areas with optimal and low levels of fluoride, respectively.

In general, studies identified by the RSI literature search reported a wide range of fluoride concentrations ranging from 0.06 ppm in Brazil [31] to >4 ppm in Iran [77]. Further to a study conducted in 2022 in Canada [403] where the reported fluoride levels in tap water was 0.1 – 1.0 ppm, other examples of fluoride concentrations relevant to the Canadian context were reported from Ireland (tap water, 0.6 – 1.0 ppm) [22], China (tap water, 0.89 – 0.91 ppm) [78], Mexico (tap water, 1.22 ±1.09 ppm) [54], and India (tap water, 0.67-0.83 [404], 1.1–2.92 [399] and 1.27 ±0.46 ppm) [62]. Only 2 studies [22, 38] reported non-significant (possible) association between high drinking water fluoride (>6 ppm) and dental fluorosis.

Although no meta-analysis was conducted for the current RSI review, an earlier review by Ihezor-Ejiofor et al [395] included a dose-response meta-analysis of 40 studies at high risk of bias (published up to that time). The results suggested that the odds of dental fluorosis increased by 2.9 for each unit increase of fluoride exposure, and at 0.4 ppm fluoride, 10% of a population (95% CI: 6%-15%) would be expected to have dental fluorosis of aesthetic concern (defined as ≥3 TFI, ≥2 TSIF, or mild or worse DFI).

#### *RSI evidence synthesis:*

Several newer studies have been published since the CADTH 2019 review, adding to the large body of literature on fluoride and dental fluorosis effects. Evidence in these new studies is consistent with previously published work for the prevalence of dental fluorosis in populations with varying levels of fluoride in drinking water.

### **Fluorosis, skeletal**

Earlier evidence on the association of fluoride with skeletal fluorosis was reported by NHMRC 2016 [9, 10] (one systematic review at 3.8 to 8 ppm and two studies of low quality at <4, 4 to 6, and >6 ppm for one study, and 1.51 to 3.71 ppm for the other study) and CADTH 2019 [2] (two studies of low quality at Canadian CWF levels). Evidence was collectively reported by CADTH 2019 as insufficient to conclude an association. The RSI literature review identified 3 cross-sectional studies with high/acceptable quality that were conducted in China [51], Ethiopia [18], and India [23] on individuals aged 10 years or older. Whereas only 1 study [18] reported a positive association between fluoride exposure and skeletal fluorosis, the 2 other studies of acceptable quality reported a possible impact [23, 51]. Reported ground water fluoride levels

included a mean of 6.8 ppm  $\pm$ 4.3 SD in one study, and a wide range  $\leq$ 1 –  $>$ 4.0 in another study. No water fluoride levels could be extracted, or extrapolated from the third study<sup>[51]</sup>.

*RSI evidence synthesis:* Based on the available literature to date, there is limited evidence for an association of skeletal fluorosis with fluoride exposures relevant to Canadian drinking water levels.

## **Genotoxicity**

There were no earlier studies identified in NHMRC 2016<sup>[9, 10]</sup> or CADTH 2019<sup>[2]</sup> that reported on the association of fluoride exposure and genotoxicity. The RSI literature search identified 2 cross-sectional studies that were conducted in China with high<sup>[24]</sup> or acceptable quality<sup>[57]</sup>. Whereas the first study<sup>[24]</sup> suggested a possible association of fluoride exposure (1.1 – 4.1 ppm) with disrupting DNA methylation, the second study<sup>[57]</sup> concluded a positive association of low-moderate water fluoride exposure (0.60 ppm) and disrupting circulating mitochondrial DNA (mtDNA) levels.

*RSI evidence synthesis:* Based on the available literature to date, there is insufficient evidence to evaluate an association of genotoxicity and fluoride exposures relevant to current Canadian drinking water levels.

## **Growth and development**

### **BMI**

There were no earlier studies identified in NHMRC 2016<sup>[9, 10]</sup> or CADTH 2019<sup>[2]</sup> that reported on the association of fluoride exposure and BMI. The RSI literature search identified an ecological study<sup>[76]</sup> with acceptable quality that was conducted on Indian children and adolescents (6-18 years old), which reported a positive and non-significant correlation between water fluoride levels (range: 0.25-9.4 ppm; average: 2.1 ppm) and BMI.

*RSI evidence synthesis:* Based on the available literature to date, there is insufficient evidence to evaluate an association of BMI and fluoride exposures relevant to current Canadian drinking water levels.

## **Childhood obesity**

There were no earlier studies identified in NHMRC 2016 [9, 10] or CADTH 2019 [2] that reported on the association of fluoride exposure with childhood obesity. The RSI literature search identified a single cross-sectional study [48] with high quality that was conducted on Chinese children and adolescents aged 7–13 years old from ground water-supplied areas. The study reported an association of low-to-moderate exposure to fluoride (0.83 ppm) with overweight status and obesity in children.

*RSI evidence synthesis:* Based on the available literature to date, there is insufficient evidence to evaluate an association of childhood obesity and fluoride exposures relevant to current Canadian drinking water levels.

## **Newborn's height and weight**

A single study of low quality was reported by NHMRC 2016 [9, 10], which reported that mothers exposed to drill water with a fluoride level of 4.7 ppm were more likely to have low birth weight newborns. Another study with low quality, as reported by CADTH 2019 [2], showed a positive correlation between drinking water fluoride and infant height and weight. The RSI literature review did not identify any additional studies for this endpoint.

*RSI evidence synthesis:* In the absence of new studies, the CADTH summary of evidence remains unchanged: Insufficient evidence for an association between water fluoridation at the current Canadian levels and newborns' weight or newborns' height.

## **Kidney diseases**

### **Kidney, dysfunction**

There were no earlier studies identified in NHMRC 2016 [9, 10] that reported on the association of fluoride and kidney dysfunction. In 2019, the review by CADTH 2019 [2] identified a single study with low quality and concluded that there was insufficient evidence on the association between CWF and kidney dysfunction.

The RSI literature search identified 4 studies with high quality and 2 studies with acceptable quality, which examined the association of fluoride exposure with kidney dysfunction [36, 44, 49,

60, 45, 73]. Four out of these 6 studies reported results consistent with a possible association [36, 44, 49, 60]. The first study [49] was cross-sectional in design that was conducted on US adolescents (12-19) as part of the NHANES survey, which suggested a possible association with complex changes in kidney functions. A second cross-sectional study [60] was conducted on Mexican adults (18-77 years old) who were exposed to high drinking water fluoride levels. The study reported a possible fluoride-associated kidney tubular dysfunction, with a likely impact on future development of chronic kidney dysfunction. A third cross-sectional study with acceptable quality [36] was conducted on men diagnosed with CKDu, and concluded a possible association with serum fluoride. A fourth Sri Lanka-based study of case-control design with acceptable quality [44] was conducted on 19-76 years old, non-dialysis, biopsy-proven CKDu adult cases. Study suggested a possible association between fluoride exposure and CKDu. These 4 studies reported kidney dysfunction at water fluoride concentrations of 0.48 ppm [49], 1.33 ppm [44], 1.5 ppm [60] and 0.68 ppm ( $\pm 0.48$ ) [36].

One cross-sectional study with high quality was conducted on 5-12 years old Mexican school children [45], and reported an inconclusive association with kidney disease of unknown origin (CKDU) at a fluoride concentration of 0.3 ppm. Another cross-sectional study conducted on Mexican children (5-12 years old) reported no association between kidney injury biomarkers and fluoride [73] at a concentration of 2.47 ppm.

*RSI evidence synthesis:* Based on the available literature to date, there is limited evidence for an association of kidney dysfunction (mainly CKDu) and fluoride exposures relevant to current Canadian drinking water levels.

## **Kidney, stones**

The review by CADTH 2019 [2] concluded there was limited evidence for an inverse association between fluoride exposure and development of kidney stones based on a single study with acceptable quality. There were no studies identified in NHMRC 2016 [9, 10] or RSI literature search that reported on the association of fluoride exposure with kidney stones.

*RSI evidence synthesis:* In the absence of new studies, the CADTH summary of evidence remains unchanged: Limited evidence for an inverse association between water fluoridation at the current Canadian levels and the incidence of kidney stones.

## **Kidney, ultrastructural**

There were no earlier studies identified in NHMRC 2016 [9, 10] or CADTH 2019 [2] that reported on the association of fluoride exposure with ultrastructural changes in the kidney. The RSI literature search identified a single study of acceptable quality, which was conducted in India on children (4-12 years old) with nephrotic syndrome minimal change disease (NS-MCD). Although the study was case-control in design, only cross-sectional analysis results relevant to the RSI review were included. The study reported a positive association between fluoride exposure and ultrastructural changes and apoptosis in human renal tubules [66]. However, no water fluoride levels were extracted or extrapolated from this identified study.

*RSI evidence synthesis:* Based on the available literature to date, there is insufficient evidence to evaluate an association of ultrastructural changes in the kidney and fluoride exposure.

## **Liver dysfunction**

There were no earlier studies identified in NHMRC 2016 [9, 10] or CADTH 2019 [2] that reported on the association of fluoride exposure with liver dysfunction. The RSI literature search identified two studies, which examined the association of fluoride exposure with liver dysfunction. The first [49] was cross-sectional in design, that examined data on US adolescents (12-19) as part of the NHANES survey, and suggested a possible association between water fluoride (0.48 ppm) and complex changes in liver functions in adolescents. Another case-control study with acceptable quality [70] was conducted on patients with dental and skeletal fluorosis in India, which reported that prolonged water fluoride (>1.5 ppm) could overwhelm the regenerative capacity of liver tissues leading to liver damage.

*RSI evidence synthesis:* Based on the available literature to date, there is insufficient evidence to evaluate an association of liver dysfunction and fluoride exposures relevant to current Canadian drinking water levels.

## **Neurologic**

### **Neurologic, Headache**

The NHMRC 2016 [9, 10] examined two studies with low quality, which did not provide a clear conclusion on the association between fluoride and headache symptoms. No studies were identified in CADTH 2019a [3]. RSI literature search identified 1 study [18] that reported a possible association between headache and paresthesia at ground water fluoride level of 6.8 ±4.3 ppm.

*RSI evidence synthesis:* Based on the available literature to date, there is insufficient evidence to evaluate an association of headache and paresthesia and fluoride exposures relevant to current Canadian drinking water levels.

### **Neurologic, Sleep-related Outcomes**

The NHMRC 2016 [9, 10] examined two studies with low quality, which did not provide a clear conclusion on the association between fluoride exposure and insomnia. CADTH 2019a [3] literature search did not identify any new studies. The RSI literature search identified a single cross-sectional study with high quality [50] that was conducted on US adolescents (16-19) as part of the NHANES survey (2015–2016). This study reported positive and significant associations between water fluoride levels (0.39 ppm) and sleep apnea, bedtime and wake time; non-significant positive associations with the recommended sleep duration and daytime sleepiness; possible and significant inverse association and snoring among males; and no association with trouble sleeping.

*RSI evidence synthesis:* Based on the available literature to date, there is insufficient evidence to evaluate an association of sleep-related outcomes and fluoride exposures relevant to current Canadian drinking water levels.

## **Reproduction**

### **Reproduction, abortion and fertility**

Two studies of low quality were identified earlier by CADTH 2019 [2], which did not provide a clear conclusion between water fluoride level and rates of abortion. There were no studies

identified in NHMRC 2016 [9, 10] or RSI literature search that reported on the association of fluoride exposure with abortion.

*RSI evidence synthesis:* In the absence of new studies, the CADTH summary of evidence remains unchanged: Insufficient evidence for an association between water fluoridation at the current Canadian levels and reproduction in women.

### **Reproduction, preterm births**

There were no earlier studies identified in NHMRC 2016 [9, 10] or CADTH 2019 [2] that reported on the association of fluoride exposure and preterm births. The RSI literature search identified a single cross-sectional study of high quality, that was conducted on US women with a live birth (2009- 2016) who responded to the PRAMS survey (Pregnancy Risk Assessment Monitoring System) [55]. The study reported that women who had dental cleaning during pregnancy and lived in a community with water fluoridation had lower prevalence of preterm births. However, no water fluoride levels could be extracted, or extrapolated from this identified study.

*RSI evidence synthesis:* Based on the available literature to date, there is insufficient evidence to evaluate an association of preterm births and fluoride exposure.

### **Reproduction, sex hormones**

There were no earlier studies identified in NHMRC 2016 [9, 10] or CADTH 2019 [2] that reported on the association of fluoride exposure and disruption of male sex hormones. The RSI literature search identified 2 cross-sectional studies of high quality that examined US children and adolescents 6–19 years old (NHANES survey) [28], and male farmers from Henan Province in China [42]. Results from the first study [28] indicated a gender- and age-specific inverse associations of fluoride in plasma and water with sex steroid hormones of total testosterone, estradiol and SHBG in U.S. children and adolescents, with a mean water fluoride level of 0.36 ppm (0.30 – 0.42). The second study [42] reported a significant inverse association between water fluoride level and serum sex hormone binding globulin (SGBH) levels but not with androgen binding protein (ABP) levels. The average fluoride concentration in villages in the high exposure group (HEG) was  $2.44 \pm 1.88$  mg/L, and in the control, low

exposure villages (LEG) was  $0.37 \pm 0.15$  mg/L. RSI also identified a relevant abstract <sup>[15]</sup> that reported a possible association with altering the hypothalamic testicular axis hormones in human males residing in high fluoride regions. There were insufficient details on the study in the published abstract.

*RSI evidence synthesis:* Based on the available literature to date, there is limited evidence for an association of levels of sex hormones and fluoride exposures relevant to current Canadian drinking water levels.

## **Thyroid dysfunction**

Evidence on the association of fluoride with thyroid gland dysfunction was reported on by NHMRC 2016 <sup>[9, 10]</sup> (3 studies of low quality) and CADTH 2019 <sup>[2]</sup> (1 study of acceptable and three studies of low quality), which concluded mixed findings, flagging insufficient evidence for this association.

The RSI literature review identified seven relevant studies, which were all of cross-sectional design, and were conducted on children and adolescents. Three studies were conducted in India <sup>[53, 61, 67]</sup>, 3 in China <sup>[20, 29, 41]</sup>, and 1 in Canada <sup>[63]</sup>. Four studies of high <sup>[20, 41]</sup> or acceptable quality <sup>[61, 67]</sup> reported a positive association with thyroid dysfunction, 1 study of high quality reported a possible association <sup>[63]</sup>, and 1 study of acceptable quality that reported a non-significant association <sup>[29]</sup> with thyroid dysfunction. These studies identified disruption of thyroid hormones at water fluoride concentrations of 0.22 ppm <sup>[63]</sup>, <1ppm <sup>[67]</sup>, 1.39 ppm <sup>[41]</sup>, and 2.88 ppm <sup>[61]</sup>. A seventh study of acceptable quality reported no association between disruption of thyroid functions and drinking water fluoride levels (0.01-2.0 ppm) <sup>[53]</sup>.

*RSI evidence synthesis:* Based on the available literature to date, there is limited evidence to evaluate the association of thyroid hormone disruption and fluoride exposures relevant to current Canadian drinking water levels.

## **Other outcomes**

### **Arsenic methylation**

There were no earlier studies identified in NHMRC 2016 <sup>[9, 10]</sup> or CADTH 2019 <sup>[2]</sup> that reported on the association of fluoride exposure and arsenic methylation. The RSI literature search

identified a single cross-sectional study of high quality that was conducted on Mexican adults. The study reported a positive association between water fluoride exposure (1.6 ppm) and increasing arsenic (As) toxicity in adults, which has been linked to adverse health outcomes such as cancer, cardiovascular diseases, diabetes and cardiometabolic risk <sup>[46]</sup>.

*RSI evidence synthesis:* Based on the available literature to date, there is insufficient evidence to evaluate an association of arsenic methylation and fluoride exposures relevant to current Canadian drinking water levels.

## **General health**

There were no earlier studies identified in NHMRC 2016 <sup>[9, 10]</sup> or CADTH 2019 <sup>[2]</sup> that reported on the association of fluoride exposure and general health. The RSI literature search identified a large cross-sectional study <sup>[75]</sup> with acceptable quality that was conducted using data on >500,000 US adolescents and adults from the National Health and Nutrition Examination Survey III (NHANES III). The study reported a lack of evidence for an effect of water fluoridation (0.3-3 ppm) on general health.

*RSI evidence synthesis:* Based on the available literature to date, there is insufficient evidence to evaluate an association of general health and fluoride exposures relevant to current Canadian drinking water levels.

## **Other non-skeletal manifestations of fluoride toxicity**

There were no earlier studies identified in NHMRC 2016 <sup>[9, 10]</sup> or CADTH 2019 <sup>[2]</sup> that reported on the association of fluoride exposure with non-skeletal manifestations of fluoride toxicity (referred to as non-skeletal fluorosis by some authors). The RSI literature search identified 2 cross-sectional studies with acceptable quality that were conducted in Ethiopia <sup>[18]</sup> and India <sup>[68]</sup>. The first one <sup>[18]</sup> reported a possible association between fluoride exposure from ground water and multiple manifestations including loss of appetite, constipation, and fatigue. Participants were 10–70 years old from rural areas who were exposed to groundwater fluoride levels with a mean concentration of  $6.8 \pm 4.3$  mg/L (range: 0.3–15.5 mg/L). The second study <sup>[68]</sup> compared individuals living in areas with high-fluoride exposure to those in normal fluoride exposure areas. The study reported that non-skeletal manifestations of fluoride toxicity

(dyspepsia, fatigue and muscle weakness) may be due to fluoride exposure through water (>1.5 ppm) or other sources like food.

*RSI evidence synthesis:* Based on the available literature to date, there is insufficient evidence to evaluate an association of the listed non-skeletal manifestations of fluoride toxicity and fluoride exposure.

## **Suicide**

There were no earlier studies identified in NHMRC 2016 <sup>[9, 10]</sup> or CADTH 2019 <sup>[2]</sup> that reported on the association of fluoride exposure and suicide. The RSI literature search identified a single relevant abstract <sup>[16]</sup>, which reported a possible association between fluoride exposure and reduction in suicide rates. However, no water fluoride levels were extracted or extrapolated from this identified abstract.

*RSI evidence synthesis:* Based on the available literature to date, there is insufficient evidence to evaluate an association of suicide and fluoride exposure.

Table 11: Summary of evolving evidence on health effects

<b>Outcome</b>	<b>NHMRC 2016</b>	<b>CADTH 2019 new evidence</b>	<b>CADTH 2019 conclusion</b>	<b>RSI 2021 new evidence</b>	<b>RSI 2021 conclusion</b>
<i>All-cause, mortality</i>	<p>1 study (N= 208,570,962, acceptable)  <i>A small reduction in incidence rate of all-cause mortality in CWF areas. Difference in rate was: - 1.3% (95% CI: -2.4%, 0.1%).</i></p>	No studies	Insufficient evidence for an association at the current Canadian CWF levels. ## Summary of evolving animal evidence

The RSI search identified new animal evidence relating to twelve primary endpoints, updating the evidence reported in two previous authoritative reviews of animal studies: Health Canada 2010 <sup>[1]</sup> and the NTP 2016 <sup>[4]</sup> draft report on neurocognitive outcomes. A summary of evidence for each outcome, based on the most recent critical review and the current review, is provided in the following sections, with emphasis on effects occurring at or below exposures (i.e., 20 ppm) relevant to current fluoride levels in Canadian drinking water.

## Neurological and cognitive outcomes

Summary based on the NTP 2020 draft report <sup>[328]</sup>: NTP systematically reviewed experimental animal studies published up until 2019 that investigated the effect of fluoride on neurodevelopmental and cognitive outcomes with priority given to learning and memory. This review also focused on mechanistically linked outcomes such as measures of thyroid function. Each included individual study was assessed for study quality using OHAT risk of bias tool. This review concluded that the evidence based on experimental animal studies was ‘inadequate’ to assess whether exposure to fluoride could affect learning and memory, particularly at human-relevant exposure levels. The primary rationale provided for this conclusion was “the inability to separate the learning and memory effects from the effects on motor activity or motor coordination”. The majority of the studies were of poor quality in which either the assessment of learning and memory was not accompanied with evaluation of motor activity to determine whether the observed changes in learning and memory could be due to motor dysfunction or to determine whether results had been affected by adverse effects on general health <sup>[392]</sup>. However, those studies that did examine both cognitive and motor deficits, “mainly found an association between fluoride exposure and both types of neurological outcomes or found no effect of fluoride exposure on either type of neurological outcome irrespective of the dose range or duration of dosing”.

*RSI updated evidence synthesis:* In the current review, a total of 3 low risk-of-bias studies with at least one test concentration  $\leq 20$  ppm (tier-1 study) and published since 2019 were identified. Although 1 study <sup>[215]</sup> found an impairment in the processes of spatial learning and memory in rats from long term fluoride exposure at 50 ppm, it possesses the same study limitations (i.e., no concurrent assessment of motor activity) identified in studies reviewed in

the draft NTP 2020 [328]. Two other low risk of bias tier 1 studies found no significant effects below 20 ppm [196, 240].

### **Endocrine including thyroid outcomes**

Summary based on Health Canada 2010 report: No studies were found examining adverse effects on thyroid at exposure concentrations below 20 ppm. Only studies under very high fluoride exposures (600 mg/L) and/or iodine imbalance (excess or deficiency) conditions were identified.

RSI updated evidence synthesis: A total of two lower risk-of-bias tier-1 studies [187, 208] that assessed changes in thyroid related to fluoride exposure at or below 20 ppm fluoride in drinking water were identified. Both studies were conducted in rats (Wistar or Long-Evans hooded) with exposure concentration ranging from 2.3 to 20 ppm fluoride and for 2 to 8 months. One study [208] did not find a significant association between increase in fluoride concentration (up to 20 ppm) and change in thyroid hormone levels (TSH, T3, or T4); the other study [187] reported statistically significant – though inconsistent across two time points – changes in thyroid hormonal levels (serum T4 increased at 2 months but not at 8 months; serum TSH unchanged at 2 months but decreased at 8 months; serum T3 unchanged; apoptosis of thyroid cells increased) in rats exposed to 4.5 and 9 mg/L fluoride. Additionally, one tier-2 study [84] found significant decline in plasma T3 and T4 levels in rats exposed to 15 mg/L fluoride for 45 days.

*RSI updated evidence synthesis:* Overall, the studies included in the current review suggest no or inconsistent evidence of thyroid dysfunction in animals exposed to fluoride in drinking water at concentrations relevant to current fluoride levels in Canadian drinking water.

### **Renal or Kidney related outcomes**

Summary based on Health Canada 2010 report: No studies found examining adverse effects on kidney at exposure concentrations below 20 ppm. Wistar mice exposed to very high fluoride concentrations (226 mg/L) during pregnancy through to the 14<sup>th</sup> day post-delivery demonstrated increase in urinary fluoride excretion (mothers and pups), increase in plasma creatinine and decrease in urinary creatinine levels. *RSI updated evidence synthesis:* Six low

to medium risk of bias animal studies [112, 116, 149, 174, 232, 282] were identified that evaluated fluoride effects on kidney function at test concentrations 20 ppm or below. These studies investigated the impact of fluoride exposure in rodents (mice or rats) at different exposure durations (chronic or sub-chronic) given a range of drinking water fluoride concentrations (ranged from 0.05 – 150 mg/L); specific outcomes measured include kidney dysfunction markers such as blood urea nitrogen (BUN) or creatinine (CRE) levels or histological analysis. Three out of six studies found some histopathological changes in kidneys (such as proximal tubule injury) but none reported any significant changes in kidney dysfunction markers such as BUN or CRE at or above test concentrations relevant to humans; except one study [232] found slight but significant increase in CRE levels after long term exposure at 20 ppm fluoride concentrations.

### **Reproductive/ Developmental outcomes**

Summary based on Health Canada 2010 report: Numerous good quality animal studies reported adverse effects on reproductive function however these effects occurred only at very high concentrations that are not relevant to current fluoride levels in Canadian drinking water or at levels that known to cause dental and/or skeletal fluorosis. Further, high quality multigeneration guideline studies didn't find effects on reproductive function from continuous exposure to fluoride in drinking water.

*RSI updated evidence synthesis:* Twelve low to medium risk-of-bias tier-1 studies were identified that evaluated adverse effects on reproductive system in experimental animal studies from fluoride exposure at or below 20 ppm [109, 114, 115, 182, 183, 210, 262, 263, 277, 284, 288, 313]. These studies reported that fluoride exposure could induce changes in the organ coefficient of the testis, sperm count, sperm abnormalities, sperm motility, sperm survival, sperm hyperactivation, fertility, testosterone levels, testicular histology and fertility indices. These effects were observed at a range of fluoride exposure concentrations (5 – 100 ppm fluoride in drinking water), different exposure durations (49 to 211 days) and in multiple rodent species (rats and mice); only one study examined effects from exposures during pre-mating, mating, gestation. The lowest concentration tested showing significant reduction in sperm quality was 5 mg/L fluoride. Overall, there was evidence of effects on male fertility, primarily decrease in

sperm quality and increased testicular damage, from fluoride exposures at concentrations relevant to current fluoride levels in Canadian drinking water.

## **Cancer**

Summary based on Health Canada 2010 report: In a cancer bioassay, no malignant tumors related to fluoride exposure were observed, in Sprague-Dawley rats or CD-1 mice exposed to 25 mg/kg bw/day NaF for 95-99 weeks, or in F344 rats exposed to 250 mg/L NaF.

*RSI updated evidence synthesis:* No animal studies evaluating the association between fluoride exposure and cancer outcomes were found.

## **Skeletal/bone related outcomes**

Summary based on Health Canada 2010 report: In a comprehensive chronic toxicity/ carcinogenicity bioassay, with F344/N rats and B6C3F1 mice exposed to drinking water containing up to 75 mg/L NaF for 2 years, the estimated NOAELs were 2.7 and 4.1 mg/kg bw/day for the female and male rats, respectively, and 5.7 and 4.9 mg/kg bw/day for the female and male mice, respectively.

*RSI updated evidence synthesis:* Three lower risk-of-bias tier-1 studies <sup>[150, 172, 258]</sup> were identified to assess the bone/skeletal related toxicity of fluoride exposure at or below 20 ppm fluoride in drinking water. Hosokawa et al. 2016 <sup>[150]</sup> reported no significant increase in any bone indexes in male and female nephrotic mice model (ICGN) exposed to NaF for 4 weeks. Kobayashi et al., <sup>[172]</sup> reported that fluoride in drinking water for 8 weeks didn't induce any significant changes in bone mineral density or bone modeling. Song et al., <sup>[258]</sup> reported increase in serum ALP, but no change in serum bone alkaline phosphatase activity, in Wistar rats exposed to 10 ppm fluoride for 15 and 30 days. Turkekul et al. <sup>[270]</sup> reported severe thinning of the epiphyseal growth plate and trabecular thickness, as well as fat accumulation in the bone marrow in a dose-dependent manner (5-50 ppm fluoride). In a few tier-2 studies, rats and mice exhibited, upon long term (84-210 days) fluoride exposure (15-50 ppm fluoride), elevated bone mineral density and serum ALP and worsened skeletal health (osteosclerosis, mild calcification of pelvic bone) <sup>[105, 106, 118, 132]</sup>.

## **Diabetes or Glucose or Lipid Metabolism related outcomes**

Summary based on Health Canada 2010 report: No animal evidence on diabetes, or any metabolism related outcomes occurred at or below 20 ppm fluoride exposure concentrations was identified.

*RSI updated evidence synthesis:* Three lower risk-of-bias tier-1 studies [194, 200, 329] were identified to assess association between diabetes or any metabolism related outcomes and fluoride exposure at or below 20 ppm fluoride in drinking water. Lupo et al. 2011, [200] reported that intake of fluoridated water from water supply (up to 15 ppm for 60 days) modified plasma insulin levels without affecting plasma glycaemia in Sprague-Dawley rats. No change in glycaemia, insulinemia, KITT, and HOMA2-IR were found in Wistar rats exposed to 10 ppm NaF for 22 days [194]. In another study [205], non-diabetic mice exposed to 10 ppm NaF had a significant reduction in the plasma glucose levels and a significant increase in the  $\beta$ -cell function.

## **Cardiovascular outcomes**

Summary based on Health Canada 2010 report: In a multigeneration rodent study, Wistar rats exposed to 0.45, 4.5, 22.5, 45 mg/L in drinking water showed significant histopathological changes in the myocardial tissues (at  $\geq 22.5$  mg/L) accompanied by increase in markers of oxidative stress such as superoxide dismutase, GSH peroxidase, and catalase.

*RSI updated evidence synthesis:* The single tier-1 study identified [207] in this review found that after being exposed to NaF for up to 15 mg/L for 4.5 months, Wistar rats with chronic kidney dysfunction had significantly increased medial vascular calcification (MVC). No experimental studies on animals with normal kidney function were identified. In one tier-2 study [108] an observed increase in blood pressure and potential endothelial damage occurred at 10 mg NaF/L in healthy Sprague Dawley rats.

## **Respiratory outcomes**

Summary based on Health Canada 2010 report: No animal evidence on respiratory outcomes were identified.

*RSI updated evidence synthesis:* No tier-1 or tier-2 study was identified.

### **Hepatic system related outcomes**

Summary based on Health Canada 2010 report: No animal evidence on hepatotoxicity was identified.

*RSI updated evidence synthesis:* Two lower risk-of-bias tier-1 studies [116, 232] were identified to assess the hepatotoxicity of fluoride exposure at or below 20 ppm fluoride in drinking water. Chattopadhyay et al. 2011, [116] reported increasing GPT level, decreasing GST levels, and extensive vacuolar degeneration in the cytoplasm and loss of integrity in the epithelium lining of central vein, on 8 weeks old Swiss albino mice, exposed at 15ppm NaF exposure for 30 to 90 days. Perera et al. 2018, [232] reported a dose-response increase in serum AST and ALP on male adult Wistar rats, exposed to up to 20 ppm NaF for 60 days. Another tier-2 study, Owumi et al., [225] showed that male Wistar rats exposed to fluoride (15 mg/L in drinking water) for 14 days had decreasing antioxidant enzyme activities, evidenced by elevated ROS & RONS levels and histopathological damage via enhancement of inflammatory responses.

### **Immune system related outcomes**

Summary based on Health Canada 2010 report: No animal evidence on immunotoxicity was identified.

*RSI updated evidence synthesis:* Two low risk-of-bias tier-1 studies were identified. Gutierrez-Salinas et al. [147] assessed the immunotoxicity of fluoride exposure at or below 20 ppm fluoride in drinking water; however, the observed changes (decreased metabolic activity or increase in apoptotic markers in macrophages) occurred only at higher concentrations (i.e., 50 mg/L). Li et al. [180] also observed immunotoxicity of fluoride exposure changes at 11.25 ppm F and above, as well as histopathological changes of the spleen (an unclear junction between the splenic cortex and medulla, and irregularly shaped cells). Another two tier-2 studies were identified [151, 279]. Wang et al. 2019 [279] reported that serum cytokine contents (IL-1 $\beta$ , IL-2, IL-6, and TNF- $\alpha$ ) was significantly decreased in Sprague-Dawley rats exposed to NaF 25 and 50 mg/L for 70 days. Hosokawa et al. 2015 [151] showed a decline in relative weights of spleens, in male BALB/c mice exposed to 1 and 5 ppm for 30 days.

## **Genotoxicity**

Summary based on Health Canada 2010 report: “Inconsistencies in the overall results of the studies on the genotoxicity/mutagenicity potential of fluoride do not allow for firm conclusions to be made regarding the genotoxic potential of fluoride although the balance of evidence for genotoxicity of fluoride does not support the view that fluoride is genotoxic in humans.”

*RSI updated evidence synthesis:* One lower risk-of-bias tier-1 study <sup>[234]</sup> was identified to assess the genotoxicity of fluoride exposure at or below 20 ppm fluoride in drinking water. It showed that increase in the percentage of aberrant metaphases and chromatid breaks was more salient in animals treated with 15 mg/L fluoride, than higher doses. One tier-2 study <sup>[233]</sup> observed significant increase in percentage of dead cells in bone marrow and in percentage of aberrant cells (cells with chromatid breaks) and chromatid breaks, in male Swiss-albino mice exposed to NaF 15 mg/L for 30 days.

## **Intestinal outcomes**

Summary based on Health Canada 2010 report: No animal evidence on intestinal outcomes was identified.

*RSI updated evidence synthesis:* No tier-1 or tier-2 studies were identified to assess the intestinal toxicity in animals exposed to fluoride at or below 20 ppm in drinking water.

## **Summary of in vitro evidence**

### **Evidence from in vitro models of humans and non-human animals**

Data abstraction from original in vitro studies is not considered; however, literature reviews covering original studies investigating fluoride induced toxicity in various in vitro models would be reviewed and summarized, for weight of evidence assessment along with animal and human data.

RSI reviewed in vitro studies to understand the mechanisms of action of fluoride in exposed animals or humans. The evidence collected from literature reviews on this subject was discussed by type of mechanism, and we summarized concentration ranges in which fluoride

induced a positive effect, e.g., oxidative stress apoptosis, ER-stress pathway activation,  $[Ca^{2+}]$  increase etc.

### **Oxidative stress**

As described, “oxidative stress is a recognized mode of action of fluoride exposure that has been observed in vitro in several types of cells and also in vivo in soft tissues such as the liver, kidney, brain, lung, and testes in animals and in people living in areas of endemic fluorosis” [330].

Reactive Oxygen species (ROS) can be generated from a variety of sources classified as exogenous and endogenous; UV irradiation, ozone and polyaromatic hydrocarbons (PAH) are key examples for exogenous sources. There are multiple sources considered as endogenous such as mitochondrial oxidative phosphorylation, xenobiotic metabolism, active peroxisomes and inflammation. Numerous studies demonstrated that one of the downstream effects of increase in release of ROS and subsequent oxidative stress is induction of cytotoxicity by activating apoptotic pathways. At cellular level, fluoride appeared to induce oxidative stress, cell cycle arrest, and apoptosis through various pathways such as inhibition of metalloproteins, organelle disruption, altered pH, and electrolyte imbalance. For example, excess NaF (up to 3 mM) showed to cause DNA damage, oxidative stress, mitochondrial agglutination and cytoskeleton damage to neuronal cell lines [331]. Several in vitro studies that demonstrated oxidative stress upon fluoride exposure were identified by searching through published review studies on this association and are summarized in

Table 12. In summary, based on these studies, fluoride (mostly as NaF salt) caused cytotoxicity or another apical endpoint via induction of oxidative stress pathway (measured as ROS levels, SOD activity, LDH release etc.) in a range of cell lines at concentrations ranging between 0.005 mM and 6 mM. These concentrations may be compared to human plasma fluoride levels.

Table 12: Characteristics of studies on oxidative stress

Reference	Cellular system	Fluoride Exposure	Endpoints assessed (positive effect)
Chen et al., 2017 [332]	Neuro-2A (mouse neuroblastoma cell line)	1 – 6 mM	Cell viability Lactate dehydrogenase (LDH) release
Zhang et al., 2015 [333]	PC 12 cells (pheochromocytoma cells)	0.005 mM	Intracellular ROS increase Apoptotic cells Cytotoxicity
Chen et al., 2017 [334]	BV-2 microglia cells	0.5 - 2 mM	Increase of IL-6 concentration Decrease of cell viability Decrease in SOD activity Increase of TNF- $\alpha$ level
Shuhua et al., 2012 [335]	BV-2 microglia cells	0.024 mM	SOD activities decreased NOS (synthesizing NO) increased
Xu et al. 2013 [336]	Human neuroblastoma SH-SY5 Y cells	0.48 - 0.95 mM	LDH levels higher
Ma et al., 2017 [337]	Human umbilical vein endothelial cells (HUVECs)	0, 4.2, and 8.4 mg/L	Oxidative stress and impaired NO production are involved in their pro-inflammatory and pro-apoptotic effects.
Grzegorzewska et al., 2020 [338]	Chicken embryonic gonads	75, 150, 300, and 600 mg/L	Increased expression of antioxidant enzymes (CAT and SOD) and nuclear respiratory factors (Nrfs)
Peng et al., 2019 [339]	F9 embryonic carcinoma cells	0, 40, 80, and 160 mg/L	Decreased Sirtuin 1 (Sirt1) protein expression, promoted the acetylation of manganese superoxide dismutase (SOD2), increased mitochondrial reactive oxygen species (mROS) production, and stimulated cytotoxicity
García-Montalvo et al., 2009 [141]	Mouse pancreatic beta-cells (betaTC-6)	0.15, 0.4, 3, 20, and 40 mg/L	Decreased SOD activity, in a dose-dependent manner, increase in the generation of O <sub>2</sub> <sup>(-)</sup> , and decreased mitochondrial membrane potential
Zhang et al., 2007 [340]	Primary rat hippocampal neurons	20, 40, and 80 mg/L	Increased malondialdehyde levels, decreased glutathione levels and glutathione peroxidase activities, reduced superoxide dismutase activity
Gao et al., 2008 [341]	Neuroblastoma (SH-SY5Y) cells	1 to 100 mg/L	Lipid peroxidation and protein oxidation in a dose-response manner

## Apoptosis

Apoptosis is genetically programmed cell death, an irreversible process of cell senescence with characteristic features different from other cellular mechanisms of death such as necrosis. There are three pathways related to fluoride exposure induced apoptosis: mitochondrion-mediated, endoplasmic reticulum (ER) stress-mediated, and death receptor-mediated pathways [330, 342-346].

## Mitochondrial dysfunction

Mitochondrial dysfunction has been shown to contribute to the occurrence of apoptosis and it is central to the apoptotic pathway [347]. There are three key types of proteins involving in this pathway: Bcl-2 family proteins, caspases, and mitochondrial pro-apoptosis proteins a rising level of intracellular reactive oxygen species (ROS), as a signal of oxidative stress, can also activate the apoptosis signaling pathway Mitochondrion is both a target of ROS and a source of the additional ROS generation [345].

Evidence show that fluoride exposure induces apoptosis by regulating the mitochondrial pathway (decreased MMP and increased ROS) in H9C2 cardiomyocytes [348], human thyroid cells [349]), and umbilical vein endothelial cells [337]. Fluoride exposure can trigger apoptosis via increasing mRNA or protein levels of Cyt c, caspase-3, and caspase-9 in HL-60 cells [350], Leydig cells [351], H9C2 cardiomyocytes [352], and human lung BEAS- 2B cells [353]. Another study found that fluoride induced cell apoptosis is accompanied by increased Bax mRNA expression level and reduced Bcl-2 expression level in PC12 cell [312].

Table 13: Characteristics of studies on mitochondrial dysfunction

Reference	Cell lines	Sodium fluoride concentrations	Findings and conclusion
Yan et al., 2015 [348]	H9c2	0, 2, 4, 8, and 16 mg/L	Induced apoptosis by increasing intracellular reactive oxygen species and downregulating mitochondrial membrane potential
Liu et al., 2014 [349]	human thyroid cells (Nthy-ori 3-1)	0, 0.4, 4.2, and 12.6 mg/L	Decreased cell viability improves the lactate dehydrogenase leakage rate, and reactive oxygen species level.
Ma et al., 2017 [337]	human umbilical vein endothelial cells (HUVECs)	0, 4.2, and 8.4 mg/L	Induced endothelial activation and apoptosis. Oxidative stress and impaired NO production are involved in their pro-inflammatory and pro-apoptotic effects.
Anuradha et al., 2001 [350]	HL-60	8.4 mg/L	Induced apoptosis by oxidative stress-induced lipid peroxidation, causing loss of deltaPsi(m), and thereby releasing cytochrome c into the

Reference	Cell lines	Sodium fluoride concentrations	Findings and conclusion
			cytosol and further triggering the caspase cascade.
Song et al., 2014 [351]	Leydig cells	0, 5, 10, and 20 mg/L	Increased expression levels of stress response factors, signal transduction components, and apoptosis-related proteins, including caspase-3/caspase-9, B-cell lymphoma 2 (Bcl-2), and Bax
Yan et al., 2017 [352]	H9c2	0, 5, 10, 20, and 40 mg/L	Increased mRNA levels of caspase-3, caspase-9, and cytochrome c. Induced apoptosis through the mitochondrial pathway.
Ying et al., 2017 [353]	human lung BEAS-2B	0, 1, 2.1, 4.2, 8.4, and 16.8 mg/L	Induced apoptosis through mitochondria-mediated signal pathways. Increased bax, caspase-3, caspase-9, p53, and the cytoplasmic CytC, decreased bcl-2 and mitochondrial CytC. Increased ROS and decreased membrane potential of mitochondria.
Liao et al., 2017 [312]	PC12	0, 2.1, and 21 mg/L	Decreased cell activity, enhanced cell apoptosis, increased c-fos, CAMKII, and Bax mRNA expression. Decreased Bcl-2 expression.

### Endoplasmic reticulum dysfunction

The endoplasmic reticulum is the main site for the folding and maturation of transmembrane, secretory, and ER-resident proteins. Accumulation of misfolded and unfolded proteins will cause ER stress, leading to the activation of self-protecting mechanisms called unfolded protein response (UPR). UPR is responsible for either relieving ER stress or inducing apoptosis [354, 355].

Fluoride exposure could induce apoptosis by triggering ER stress through upregulated GRP78, PERK, phosphorylation-eukaryotic initiation factor 2 $\alpha$  (p-eIF2 $\alpha$ ), and CHOP in Sertoli cells <sup>[296]</sup> and human thyroid follicular epithelial cells <sup>[349]</sup>. Studies on mouse ameloblast-derived LS8 cells showed that fluoride exposure could induce caspase-dependent apoptosis through overexpression of PERK, eIF2 $\alpha$ , IRE1, activation of Xbp-1, BiP/GRP78, GADD153/CHOP, and JNK, which in turn inducing ER stress and UPR <sup>[356-358]</sup>.

Table 14: Characteristics of studies on endoplasmic reticulum dysfunction

Reference	Cell lines	Sodium fluoride concentrations	Findings and conclusion
Yang et al., 2015 <sup>[296]</sup>	Sertoli cells	0, 6, 12 and 24 mg/L	Decreased cell viability and induced apoptosis. Increased ER stress by up-regulating glucose-regulated protein 78 kDa (GRP78), PKR-like ER kinase (PERK), phosphorylation of eukaryotic translation initiation factor 2 $\alpha$ (p-eIF2 $\alpha$ ) and CCAAT/enhancer-binding protein-homologous protein (CHOP)
Liu et al., 2014 <sup>[349]</sup>	human thyroid cells (Nthy-ori 3-1)	0, 4.2 mg/L	Induced cytotoxicity related to IRE1 pathway-induced apoptosis.
Sharma et al., 2008 <sup>[356]</sup>	ameloblast-derived LS8	0, 5.1, 10.5, 21, and 42 mg/L	Induced ER stress response interfering with protein synthesis and secretion. Extracellular secretion of SEAP decreased in a linear, dose-dependent manner.
Sharma et al., 2010 <sup>[357]</sup>	ameloblast-derived LS8	0, 2.1 mg/L	Increased cell stress by phosphorylating stress-related proteins, PERK, eIF2 $\alpha$ , JNK and c-jun
Kubota et al., 2005 <sup>[358]</sup>	ameloblast-derived LS8	0, 21, 42, 63, and 84 mg/L	Inhibited cell growth at low dose, whereas higher doses induced ER stress and caspase-mediated DNA fragmentation.

## Death receptor-mediated pathways

Fluoride can induce apoptosis by regulating Fas ligand (FasL)/Fas signaling pathway and tumor necrosis factor- $\alpha$  (TNF- $\alpha$ )/tumor necrosis factor-receptor-1 (TNF-R1) signaling pathway, which belongs to the death receptor pathways.

Fluoride exposure could induce apoptosis by upregulating the protein expression of FasL, Fas, caspase-8, caspase-3, and cleaved PARP in the primary rat ameloblasts [359], human neuroblast cells [360], and human gingival fibroblasts [361]. Studies using mice splenic lymphocytes show that fluoride exposure cause ER stress and UPR [362] and decreasing mitochondria transmembrane potential, up-regulating Bax, Bak, Fas, FasL, caspase 9, caspase 8, caspase 7, caspase 6 and caspase 3, and down-regulating Bcl-2 and Bcl-xL [363].

Table 15: Characteristics of studies on death receptor-mediated pathways

Reference	Cell lines	Sodium fluoride concentrations	Findings and conclusion
Wang et al., 2016 [359]	primary rat ameloblast	0.4, 0.8, 1.6, 3.2, and 6.4 mmol/L	Induced apoptosis via activation of FasL/Fas signaling pathway and diminished secretion of AMBN
Deng et al., 2016 [362]	mice splenic lymphocytes	0, 4.2, 8.4, and 16.8 mg/L	Induced apoptosis and caused ER stress by up-regulating protein expression levels of glucose-regulated protein 78 (BiP) and glucose-regulated protein 94 (GRP94), and by activating unfolded protein response (UPR).
Deng et al., 2016 [363]	mice splenic lymphocytes	0, 4.2, 8.4, and 16.8 mg/L	Induced apoptosis by decrease of mitochondria transmembrane potential, up-regulation of Bax, Bak, Fas, FasL, caspase 9, caspase 8, caspase 7, caspase 6 and caspase 3 protein expression, and down-regulation of Bcl-2 and Bcl-xL protein expression.

Reference	Cell lines	Sodium fluoride concentrations	Findings and conclusion
Lee et al., 2008 [361]	human gingival fibroblasts	5, 10, 20, 30, and 40 mmol/L	Induced apoptosis through the Bcl-2 family and death receptor-mediated pathway. Increased cytochrome c release from the mitochondria into the cytosol, enhanced the caspase-9, -8 and -3 activities, the cleavage of poly (ADP-ribose) polymerase (PARP), and up-regulated the voltage-dependent anion channel (VDAC).
Xu et al., 2011 [360]	human neuroblastoma (SH-SY5Y)	0, 20, 40, and 80 mg/L	Induce apoptosis by increasing caspase-3 and mRNA expression levels for Fas, Fas-L, and caspases (-3 and -8).

### Na, K-ATPase

Sodium, potassium-activated adenosine triphosphatase (Na, K-ATPase) is a member of the P-type family of active cation transport proteins, which maintains sodium and potassium homeostasis in animal cells by transporting Na<sup>+</sup>-ions to the outside and K<sup>+</sup>-ions to the inside of the cell, at the expense of ATP. Na, K-ATPase is responsible for the electrochemical gradient across the plasma membrane and the regulation of the cellular ionic homeostasis. In addition, Na, K-ATPase activity plays a crucial role in the function of neurotransmitter transporters, which are essential for regulating neurotransmitter signaling and homeostasis. [364, 365].

Fluoride exposure inhibits the activity of Na, K-ATPase through multiple pathways. In summary, fluoride has been shown to upregulate PKC, cAMP, cGMP, NO, Pi, PLA2, AA, PGE2, dopamine, glucose and PTH. The formation of these biomarkers inhibits Na, K-ATPase activity.

Table 16: Characteristics of studies on Na, K-ATPase

Reference	Cell lines	Sodium fluoride concentrations	Findings and conclusion
Gutowska et al., 2010 [366]	human monocytic line THP-1	0.4, 1.2, 2.4, 4.0 mg/L	decreased the amount of synthesized cellular ATP and increased formation of ROS and apoptosis in a dose-dependent pattern
Agalakova & Gusev 2012 [367]	rat erythrocytes	0, 4, 20, 80, 400 mg/L	Dose- and time-dependent decline of ATP a, diminishing to extremely low levels within 24h.
Cittanova et al., 2002 [368]	rabbit kidney thick ascending limb cells	0, 40, 200, and 400 mg/L	Depletion of Na-K-ATPase activity and renal mitochondrial dysfunction

### Inflammatory response

Inflammation is the body's immune system's response to an irritant, e.g., infection or tissue damage. The function of inflammation is to eliminate the initial cause of cell injury, clear out necrotic cells and tissues damaged from the original insult and the inflammatory process, and initiate tissue repair. Chronic inflammation plays an important role in the development of chronic conditions, e.g., diabetes, atherosclerosis, cardiovascular disease, allergies, and COPD [330, 342, 343].

Studies have shown that fluoride exposure can promote inflammatory response via increasing oxidative stress and ROS in human umbilical vein endothelial cells (Ma 2017), human monocytic line THP-1 [366], and RAW 264.7 murine macrophage line [369]. Fluoride related phosphorylation of c-Jun NH (2)-terminal kinase (JNK) was involved in the pro-inflammatory response in the MDPC-23 odontoblast-like cells ([370]) and human ameloblast lineage cells ([371]).

Table 17: Characteristics of studies on inflammatory response

Reference	Cell lines	Sodium fluoride concentrations	Findings and conclusion
Ma et al., 2017 [337]	human umbilical vein endothelial cells (HUVECs)	0, 4.2, and 8.4 mg/L	Endothelial activation and apoptosis. Oxidative stress and impaired NO production are involved in their pro-inflammatory and pro-apoptotic effects.
De la Fuente et al., 2016 [369]	RAW 264.7 murine macrophage line	5, 10, 25, and 65 mg/L	Increased ROS, redox imbalance, lipid peroxidation, and cytokines Il6 and Mip2
Gutowska et al., 2010 [366]	human monocytic line THP-1	0.4, 1.2, 2.4, 4.0 mg/L	Depleted ATP and increased ROS and apoptosis in a dose-dependent pattern
Karube et al., 2009 [370]	MDPC-23 odontoblast-like cells	200 mg/L	phosphorylation of c-Jun NH(2)-terminal kinase (JNK) and p38, exhibited caspase-3 activation, cleavage of poly(ADP-ribose) polymerase, DNA fragmentation, and an increase in cytoplasmic nucleosomes
Zhang et al., 2007 [371]	human ameloblast lineage cells	0.4 mg/L	Decreased MMP-20 protein levels and related to suppression of JNK/c-Jun phosphorylation.
Zhang et al., 2007 [340]	primary rat hippocampal neurons	20, 40, and 80 mg/L	Induced S-phase cell-cycle arrest, up-regulation of NF-kappaB and DNA damage

## VIII. Candidate endpoints and Bradford Hill considerations

### Selection of new candidates for the most sensitive endpoint(s)

In reviewing evidence for the link between fluoride in drinking water and all health endpoints, a number of provisional candidate endpoints were considered as the basis for updating the HBV, based on identifying a most sensitive endpoint). In evaluating the body of evidence identified in the RSI literature review, the following hierarchical approach was used for

selection of candidate endpoints. A health endpoint was chosen for further examination (using Bradford Hill's considerations for causality) <sup>[8]</sup> based on the following criteria:

1. In the human stream of evidence for a specific endpoint:
  - a. The endpoint was of concern (either serious or severe)
  - b. There was consistent evidence of an association across studies
  - c. The association occurred in the studies at a level below that of current municipal water supplies or close to this exposure level (not higher than 2 ppm)
  - d. Studies were of reasonable quality (high or acceptable)
2. If the human stream of evidence was inconclusive for a specific endpoint, but in the animal stream of evidence:
  - a. There was consistent evidence of an association in Tier-I animal studies
  - b. The association occurred in the studies at an exposure level (less than 20 ppm F) relevant to current fluoride levels in Canadian drinking water

After consideration of all evidence identified in the updated literature review, consolidated with earlier reviews from Health Canada, CADTH, NTP, several authoritative reviews, and numerous published peer-reviewed systematic reviews, four endpoints were selected based on considerations of the overall evidence and whether these effects were plausibly occurring at exposure levels close to fluoride exposure levels in the Canadian context.

The four endpoints identified as candidates for most sensitive endpoint (with the exception of dental fluorosis) were:

- Cognitive dysfunction (specifically, reduced IQ score)
- Thyroid dysfunction
- Kidney dysfunction
- Male sex hormone alterations

### **Bradford Hill considerations for causality**

For each of the selected candidate endpoints, relevant human, animal, and in vitro evidence was organized and evaluated along the nine Bradford Hill considerations <sup>[8]</sup>. While avoiding

any misapplication of these considerations as hard rules of evidence, the review attempted to qualify how credible the associations were to support a claim of causality. As Hill remarked, “What [the nine viewpoints] can do, with greater or less strength, is to help us to make up our minds on the fundamental question—is there any other way of explaining the set of facts before us, is there any other answer equally, or more, likely than cause and effect?” [8]. The considerations include the following: strength of association, consistency, specificity, temporality, biological gradient, plausibility, coherence, experiment, and analogy. In weighing evidence of causality, the review drew from human, tier-I and tier-II animal, and in vitro streams of evidence. Only evidence from original studies of high and acceptable quality was included in the evaluation of each endpoint. To support each of the considerations, evidence was cited where available from the NHMRC 2016, [9, 10], CADTH 2019 [2, 3], and the current RSI update. The consideration for “strength of association” was only assessed based on studies reporting positive or possible associations. For the “consistency” consideration, all relevant studies were included irrespective of the nature of the reported association.

### Reducing IQ scores

NHMRC 2016 [9, 10] identified a study of acceptable quality [372], which reported a statistically significant negative correlation between drinking water fluoride and IQ. CADTH 2019 identified one study of acceptable quality (no association), and 5 studies of low quality (mixed findings). RSI identified 18 studies of high or acceptable quality that reported a positive/possible association between reduced IQ scores and water fluoride [40, 41, 64, 69, 70, 76, 401, 405, 413-416], or urinary fluoride levels [59, 71, 409, 417-419]. Based on the available literature to date, the accumulating body of evidence suggests a positive association of reduced IQ scores for children and fluoride exposures relevant to current Canadian drinking water levels.

The available evidence demonstrated a **moderate to strong magnitude (strength) of association** between fluoride and neurocognitive effects with **consistent** evidence across studies for the impact on children’s IQ at fluoride exposures relevant to current Canadian drinking water levels. Fluoride appears to play a role in the induction of a range of adverse health outcomes, and is **not specific** to a single health effect. Although a **temporality** cannot be evaluated in the available cross-sectional studies of the potential health effects of fluoride, this condition is satisfied in two large cohort studies showing reduction in children’s IQ scores.

Significant **increasing exposure-response relationships** between fluoride in drinking water and reduction in IQ scores were noted in seven epidemiologic studies. Fluoride is known to dysregulate the activity of certain enzymes in relation to IQ [70]. However, at this time **no specific mechanisms** could be determined for fluoride effects on learning and memory or other neurodevelopmental or cognitive outcomes. Results from this assessment of the included studies are summarized in Section 6 of the Supplementary Material.

Table 18: Hill’s consideration of causality for fluoride and IQ reduction

<b>Criterion</b>	<b>Summary of recent evidence</b>
<b>Strength of association</b>	<ul style="list-style-type: none"> <li>• A study of acceptable quality examined by NHMRC [372] reported a significant negative correlation between IQ and drinking water fluoride levels. A reduction of 6.7, 11.2, 10.2 in performance, verbal and full IQ scores, respectively, was observed per increase in log fluoride values [372].</li> <li>• Although CADTH did not consider the Canadian cohort study conducted by Green et al [326] to be of acceptable quality, the study was subsequently assessed by the 2020 [238] and 2022 [420] NTP draft reports as having an overall low risk of bias. This study showed a positive association between higher maternal fluoride intake and reduction in IQ. A reduction of 3.66 points was reported per 1 mg increase in daily maternal intake of fluoride.</li> <li>• RSI identified 18 new studies [40, 41, 59, 64, 69-71, 76, 401, 405, 409, 413-419], which provided statistically significant results supporting a positive/possible association of reduced IQ levels in response to increasing exposure to water fluoride. Two studies reported no association between reduction of IQ scores and drinking water [398], or non-significant frequency differences among urinary fluoride levels [29].</li> <li>• Three studies [40, 69, 418] reported that an increment of 0.5 mg/L in water fluoride concentration corresponded to: <ul style="list-style-type: none"> <li>▪ A 9.3- and a 6.2-point reduction in performance IQ in formula-fed and breastfed children, respectively. Such an association remained significant upon controlling for fetal fluoride exposure [40].</li> <li>▪ A 40% reduction in the odds of having excellent IQ in those exposed to low fluoride levels (0.20-1.40 mg/L) [69].</li> <li>▪ A drop of 2 points in full-scale IQ scores [418].</li> </ul> </li> <li>• A more recent study that used the same cohort (MIREC) reported an association between children’s performance IQ and fluoride exposure during the perinatal period and into early childhood. Such an association was reported to differ</li> </ul>

between boys and girls across the different exposure periods, though more validation is proposed by the authors [409].

- Another recent study [419] examined prenatal fluoride exposure in a small mother-child birth cohort in Spain: Results in boys suggest improved scores in cognitive domains with maternal urinary concentrations.

**Consistency**

- A total of 15 RSI-identified studies [40, 41, 59, 69, 71, 76, 401, 405, 409, 413-419] and 1 earlier study [372] of high/acceptable quality concluded a positive association with reduced IQ<sup>32</sup> levels in children/adolescents.
- Two RSI-identified studies [64, 70] concluded a possible positive association, and 1 reported a non-significant association [29] with reducing IQ scores.
- Three RSI-identified studies [54, 75, 398] and 3 earlier [373-375] studies of high/acceptable quality reported no association
- Within the 18 RSI-identified studies showing a positive/possible association, the directionality of association did not differ by study design (12 studies were cross-sectional, 5 were cohorts and 1 was a case-control study), geographic location (6 in China, 3 in India, 2 in each of Canada and Mexico, and 1 in each of Indonesia, Pakistan, Spain and Sudan), studied population (12 studies in children and/or adolescents, 5 in mother-child pairs and 1 that examined patients of all ages), or sampling time-frame.

**Specificity**

Fluoride appears to play a role in the induction of a range of adverse health outcomes, and reduction in IQ levels can be caused by a number of risk factors including exposure to toxic factors other than fluoride.

**Temporality**

Out of those that showed positive or possibly positive association, there were different follow up durations reported in two cohort studies

- Four cohort studies [71, 409, 418, 419] reported an association of maternal fluoride exposure and reduced IQ levels in their offspring, where the long follow up period (at ages 1, 4 then at age 6-12) allowed a reasonable assessment of temporality
- Another cohort study [40] reported on the association of water fluoride exposure in newborns using breast milk or formula, where IQ was measured at 3-4 years old.
- Fifteen other studies [29, 41, 59, 64, 69, 70, 76, 372, 401, 405, 413-417] that showed positive or possibly positive association were cross sectional, whereby an inference of causality cannot be concluded.

<sup>32</sup> IQ: involving scores of different IQ tests, or the use of proxies to IQ such as school performance, school tests

**Biological gradient  
(exposure-response)**

- Nineteen studies [40, 41, 59, 64, 69-71, 76, 372, 401, 405, 409, 413-419] provided statistically significant exposure-response relationship supporting a positive/possible association between exposure to fluoride and lower IQ levels, with varying categories of exposure (continuous vs. categorical).
- One study [70] reported a change in the serum levels of two enzymes (AChE and ATPase/Na<sup>+</sup> K<sup>+</sup> ATPase), which upregulate IQ-related neurological operations, in response to fluoride exposure levels as measured by the severity of fluorosis diagnosis (mild, moderate, severe)
  - AChE: Controls: 6.29 ± 0.68; Mild: 4.64 ± 0.54; Moderate: 4.11 ± 0.4; Severe: 3.78 ± 0.35
  - ATPase/Na<sup>+</sup> K<sup>+</sup> ATPase: Controls: 2.41 ± 0.34; Mild: 2.56 ± 0.31; Moderate: 2.64 ± 0.29; Severe: 2.87 ± 0.4
- Another study by Wang 2020 [41] reported a change in IQ scores per 1 mg/L increment of water fluoride (continuous) or compared to a reference quartile.
  - Continuous:  $\beta = -1.587$  (-2.607, -0.568), p-value= 0.002
  - Quartiles: IQ scores,  $\beta =$  (95% CI), p-value
    - Quartile 1 ( $\leq 0.70$ ): reference
    - Quartile 2 (0.70–1.00):  $\beta = -0.506$  (-3.764, 2.753), p-value= 0.761
    - Quartile 3 (1.00–1.90):  $\beta = -3.065$  (-5.636, -0.493), p-value= 0.020
    - Quartile 4 ( $> 1.90$ ):  $\beta = -3.471$  (-6.108, -0.835), p-value= 0.010

**Biological  
plausibility**

- Fluoride has reportedly been capable of crossing the blood brain barrier with the subsequent accumulation in brain tissues [69]. Animal evidence showed fluoride in excess is capable of reducing the “fluidity of the synaptic membrane of the hippocampus in rats” leading to hippocampal neuronal impairment and neurodegenerative changes, resulting in impaired learning and memory [69]. Such neurologic/cognitive effects are more pronounced in children compared to adults due to the former’s relatively less brain capacity to clear the toxicant (fluoride) burden [69].
- Other proposed biological mechanisms include a direct fluoride effect on the activity of PON1 enzyme via oxidative stress, and/or inactivation of various enzymes (PON1, Na<sup>+</sup>-K<sup>+</sup> ATPase and ALAD) [70].
- Human studies also reported on the possibility of fluoride to cross the placental barrier from the mother to her developing fetus [71], or via breastfeeding to her newborn [40].
- Infants who are fed formula reconstituted with fluoridated water have approximately three to four times greater exposure to fluoride than adults on a per

	<p>body-weight basis. Formula-fed infants residing in fluoridated areas have an approximate 70-fold higher fluoride intake than exclusively breastfed infants <sup>[40]</sup></p> <ul style="list-style-type: none"> <li>• However, based on the draft 2020 NTP <sup>[328]</sup> review of evidence on mechanism of action related to fluoride induced neurocognitive effects, the available data is “too general” or “cannot necessarily be attributed to effects on learning and memory or other cognitive functions”. Therefore, at this time no specific mechanism could be determined for fluoride effects on learning and memory or other neurodevelopmental or cognitive outcomes.</li> </ul>
<b>Coherence</b>	<p>Coherence with previous evidence cannot be assessed based on the findings:</p> <ul style="list-style-type: none"> <li>• No specific mechanisms were directly linked to fluoride and IQ</li> <li>• Non-human evidence was inconclusive/inadequate</li> </ul>
<b>Experimental evidence</b>	<ul style="list-style-type: none"> <li>• There has been no experimental evidence generated from human studies.</li> <li>• The most recent systematic review of experimental evidence<sup>33</sup> found that the animal data were inadequate to evaluate the effects of fluoride on learning and memory due to reasons such as difficulty in parse out the observed learning and memory effects from the effects on motor activity or motor coordination and concerns of study quality. Additionally, one of the highest quality experimental studies <sup>[208]</sup> found no fluoride treatment related effects on learning, memory or motor activity in rats provided with up to 20 ppm concentration in drinking water</li> <li>• This review concluded that “the experimental animal body of evidence does not contribute to confidence in conclusions derived from human epidemiological studies with respect to effects on human IQ. Although the evidence supports an association between fluoride exposure and neurodevelopmental effects, the data are not sufficient to support the primary effect evaluated in children (i.e., IQ) nor is it sufficient to support a conclusion on cognitive effects in adults especially in the absence of additional adult human data”</li> </ul>
<b>Analogy</b>	No suitable analogies identified

<sup>33</sup> US NTP (2020) conducted a systematic review (including risk of bias assessment) of evidence on F induced neurodevelopmental and cognitive effects in experimental studies (non-human animals)

## Thyroid dysfunction

CADTH 2019 [2] identified a study of acceptable quality [376], which reported no association between drinking water fluoride and thyroid function. The RSI examination of eligible studies identified 5 studies of high or acceptable quality that reported a positive/possible association of thyroid dysfunction with water fluoride [41, 61, 63, 67] or urinary fluoride levels [20]. Cui and Colleagues [29] reported a non-significant association between thyroid dysfunction and urinary fluoride levels. A seventh study reported no association between thyroid dysfunction and water [53]. Based on the available literature to date, there is limited evidence to evaluate the association of thyroid hormone disruption and fluoride exposures relevant to current Canadian drinking water levels.

The scarce human evidence demonstrated a **moderate magnitude (strength) of association** between fluoride and dysregulation of thyroid hormones at fluoride exposures relevant to current Canadian drinking water levels. Fluoride appears to play a role in the induction of a range of adverse health outcomes, and is **not specific** to a single health effect. **Temporality** cannot be evaluated as the available evidence is entirely based on cross-sectional studies. **Exposure-response relationships** between fluoride and dysregulation of thyroid hormones were reported in four studies with variable levels of statistical significance. Whereas multiple mechanisms were discussed in the identified studies, **no specific mechanisms** could be confirmed for explaining the impact of fluoride on thyroid hormone dysregulation. Scarce **experimental evidence** reported inconsistent results for thyroid dysfunction. Results from the included studies are summarized in Section 6 of the Supplementary Material.

Table 19: Hill's consideration of causality for fluoride and thyroid dysfunction

<b>Criterion</b>	<b>Summary of Evidence</b>
<b>Strength of association</b>	<ul style="list-style-type: none"><li>• Six studies of high/acceptable quality reported results demonstrating a positive/possible association between thyroid dysfunction and water [41, 61, 63, 67] or urinary fluoride [20].</li><li>• One study [61] reported a higher percent thyroid hormone level derangement in fluorosis-endemic areas (67.5%) compared to non-endemic areas (54%), and a significant increase in mean TSH (endemic: 3.849 µIU/m; non-endemic: 2.588 µIU/m, p = 0.02). Non-significant derangements were reported for mean free T3,</li></ul>

and free T4 levels among participants from a fluorosis-endemic area compared to a fluorosis non-endemic area.

- Another study [67] reported on levels of free T3, free T4, and TSH by villages belonging to one of four groups based on the fluoride levels in drinking water. These levels range from <1 ppm (group 1), 1-1.9 ppm (group 2), 2-2.9 ppm (group 3) and >4 ppm (group 4). Derangement of TSH (range of normal values: 0.5–2.5  $\mu\text{IU/mL}$ ) has been shown in all groups. However, only group 1 (TSH: 0.4-2.99  $\mu\text{IU/mL}$ ) and group 2 (TSH: 0.29-3.76  $\mu\text{IU/mL}$ ) were relevant to Canadian water fluoride levels.
- The third study [41] reported a change in thyroid hormone levels per 1 mg/L increment of water fluoride (continuous) or compared to a reference quartile. Only hormones with significant results are listed below.

#### **TT4 ( $\mu\text{g/dL}$ )**

- Continuous:  $\beta = -0.083$  (-0.181, 0.015), p-value= 0.097

  - P-trend: 0.009

#### **TSH ( $\mu\text{IU/mL}$ )**

- Continuous:  $\beta = 0.127$  (0.014, 0.241), p-value= 0.028
- Quartiles:  $\beta =$  (95% CI), p-value
  - Quartile 1 ( $\leq 0.70$ ): reference
  - Quartile 2 (0.70–1.00):  $\beta = -0.154$  (-0.517, 0.209), p-value= 0.404
  - Quartile 3 (1.00–1.90):  $\beta = 0.236$  (-0.005, 0.522), p-value= 0.106
  - Quartile 4 (> 1.90):  $\beta = 0.306$  (0.012, 0.600), p-value= 0.041
  - P-trend: 0.019

	<ul style="list-style-type: none"> <li>• A fourth study <sup>[63]</sup> reported that every 1mg/L increment of urinary fluoride (in iodine-deficient adults) was associated with a 0.35 mIU/L increase in TSH [95% CI: 0.06, 0.64, p-value: 0.01, one-tailed].</li> </ul>
<b>Consistency</b>	<ul style="list-style-type: none"> <li>• Four studies <sup>[41, 61, 63, 67]</sup> found a positive association between thyroid dysfunction and higher exposure to water fluoride.</li> <li>• Two additional studies reported a possible <sup>[63]</sup>, or a non-significant association <sup>[29]</sup> between urinary fluoride levels and thyroid dysfunction.</li> <li>• Within studies showing a positive/possible association, the directionality of association did not differ by study design (all studies were cross-sectional), geographic location (two in India and one in each of Canada and China), studied population (three studies in children/adolescents and one included all ages), or sampling timeframe.</li> <li>• Two additional studies of acceptable quality identified by CADTH 2019 <sup>[376]</sup> and RSI <sup>[53]</sup> reported no association between fluoride and thyroid function.</li> </ul>
<b>Specificity</b>	<p>Fluoride appears to play a role in the induction of a range of adverse health outcomes, and dysregulating thyroid hormone levels can be caused by a number of risk factors including exposure to toxic factors other than fluoride.</p>
<b>Temporality</b>	<p>All of the four studies that suggest a positive/possibly positive association were of cross-sectional study designs, whereby an inference of causality cannot be inferred.</p>
<b>Biological gradient (exposure-response)</b>	<ul style="list-style-type: none"> <li>• Six studies reported results supporting a positive/possible association between thyroid dysfunction in association with either water fluoride levels as categories <sup>[61, 67]</sup>, or on a continuous scale <sup>[41, 63]</sup>, or using urinary fluoride levels <sup>[20, 29]</sup>. <ul style="list-style-type: none"> <li>• One study reported on four groups of exposure, and identified a consistent increase in mean levels of free T3, free T4, and TSH per increase in concentrations of fluoride in water <sup>[67]</sup>.</li> <li>• Another study reported that each 1mg/L increment of water fluoride is associated with an increase in TSH, FT3 and TT3, and a decrease in FT4 and TT4. However, the effect estimate for TSH was only statistically significant before correcting for multiple testing <sup>[41]</sup>.</li> <li>• A third study <sup>[61]</sup> reported a higher thyroid hormone level derangement in fluorosis-endemic areas compared to non-endemic areas. This derangement was significant for TSH and non-significant for FT3 and FT4 levels.</li> <li>• The study by Malin et al. <sup>[63]</sup> reported that each 1mg/L increment of urinary fluoride (in iodine-deficient adults) is associated with a 0.35 mIU/L increase in TSH.</li> </ul> </li> </ul>

<b>Biological plausibility</b>	<ul style="list-style-type: none"> <li>• As halogens of lower atomic weight are capable of displacing halogens of higher atomic weight, fluoride (fluorine) can displace iodine from the body. Such displacement thus interferes with iodine uptake by the thyroid gland, leading to its dysfunction and increased secretion of the pituitary TSH hormone to stimulate the thyroid to produce more thyroid hormones [63, 67].</li> <li>• The effect of fluoride on thyroid function may depend on nutritional status and iodine deficiency. In the Canadian context, iodine deficiency is unlikely given that the intake exceeds 1mg/day due to the use of iodized salt [1]. However, the evidence also suggests that the effect of fluoride on the thyroid gland can occur independently of iodine [41].</li> <li>• Interference of fluoride with Na/K-ATPase and iodothyronine deiodinase: two enzymes that are required for proper thyroid functioning [63].</li> <li>• Fluoride may inhibit the prolactin hormone, which promotes thyroidal iodine uptake, lowers T4 secretion and inhibits stimulatory effects of exogenous TSH [63].</li> <li>• Fluoride is a structural analog of thyroid stimulating hormone (TSH) and able to bind to TSH receptors leading to change in TSH levels and changes in secretion of thyroid hormones (by altering the regulation of hypothalamus-pituitary-thyroid axis)</li> <li>• The other plausible mechanism by which excess fluoride may affect thyroid structure and function is to induce endoplasmic reticulum stress pathways and subsequent apoptosis leading to cell death and changes in thyroid follicle morphology</li> </ul>
<b>Coherence</b>	<p>Coherence with previous evidence cannot be assessed based on the findings:</p> <ul style="list-style-type: none"> <li>• No specific mechanisms were directly linked to fluoride and thyroid dysfunction</li> <li>• Animal evidence was inconclusive</li> </ul>
<b>Experimental evidence</b>	<ul style="list-style-type: none"> <li>• There has been no experimental evidence generated from human studies.</li> <li>• Two experimental studies [187, 208] were identified, which evaluated fluoride effects on thyroid function (changes in thyroid hormone levels) at test concentrations required to achieve comparable blood fluoride levels in humans exposed to drinking water in Canada and are of lower risk of bias (more details are provided in the table containing results from selected animal studies)</li> <li>• Out of two studies (both were rat chronic studies), one study didn't find an association between increase in fluoride concentration and change in thyroid hormone levels; the other study reported inconsistent evidence (across two time points) on small but significant change in TSH and serum T4 levels.</li> </ul>
<b>Analogy</b>	<p>No suitable analogies identified</p>

## Kidney dysfunction

No studies from NHMRC were found, and only one study with low quality from CADTH 2019 was identified where no conclusion could be drawn due to methodological limitations and lack of statistical analysis. The RSI examination identified four new studies [36, 44, 49, 60] of high or acceptable quality that reported a possible association between water fluoride and kidney dysfunction. Two other studies reported either inconclusive [45] or no association [73]. Based on the available literature to date, there is limited evidence for an association of kidney dysfunction (mainly CKDu) and fluoride exposures relevant to current Canadian drinking water levels.

The available human evidence demonstrated a **moderate magnitude (strength) of association, with weak consistency** between fluoride and multiple kidney injury biomarkers at fluoride exposures relevant to current Canadian drinking water levels. The effects of fluoride appear to be **not specific** to one adverse health outcome. **Temporality** cannot be evaluated as the available evidence is entirely based on cross-sectional studies. **Exposure-response relationships** between fluoride exposure and kidney dysfunction were reported in four studies with variable levels of statistical significance. Although fluoride has been reported to impact the level of multiple kidney biomarkers, **no specific mechanisms** could confirm the impact of fluoride on the kidney functions. **Experimental evidence** showed some significant histological kidney alterations in association with fluoride exposure. Results from the included studies are summarized in Section 6 of the Supplementary Material.

Table 20: Hill's consideration of causality for fluoride and kidney dysfunction

<b>Criterion</b>	<b>Summary of Evidence</b>
<b>Strength of association</b>	<ul style="list-style-type: none"><li>• Four studies [36, 44, 49, 60] of high/acceptable quality reported results demonstrating a possible association between kidney dysfunction and fluoride exposure.<ul style="list-style-type: none"><li>• One study [60] reported a significantly positive association for each unit increase in water fluoride (mg/L) with ALB (<math>\beta=1.20 \mu\text{g/mL}</math>), Cys-C (<math>\beta=0.03 \text{ mg/mL}</math>), OPN (<math>\beta=0.10 \text{ mg/mL}</math>), TFF-3 (<math>\beta=2.88 \text{ ng/mL}</math>). Change in CLU, KIM-1, and eGFR was non-significant.</li><li>• Another study reported an inverse association per each 1mg/L increase in water fluoride with BUN concentration (<math>\beta=-0.93 \text{ mg/dL}</math>, [-1.44, -0.42], <math>p=0.007</math>), whereas change in eGFR and ACR were non-significant.</li></ul></li></ul>

	<p>Additionally, a positive association was observed with SUA (non-significant) [49].</p> <ul style="list-style-type: none"> <li>• A third study [44] reported a significant increase in serum fluoride of 1.43 (0.47–9.58) in CKDu patients compared to 1.07 (0.51–1.92) in controls. Similarly, a significant increase was reported for urinary fluoride as 1.53 ([0.45–6.92) in CKDu patients compared to 1.26 (0.36–3.80) in controls.</li> <li>• The fourth study [36] also reported that CKDu patients showed significantly higher serum fluoride concentrations than the healthy controls (p-value: &lt;0.05).</li> </ul>
<b>Consistency</b>	<ul style="list-style-type: none"> <li>• Four studies [36, 44, 49, 60] suggested a possible association between kidney dysfunction and fluoride exposure.</li> <li>• Within studies showing a possible association, 3 studies were cross-sectional [36, 49, 60] and 1 was a case-control [44], geographic location included Mexico, Sri Lanka, and United States, and the studied population involved children/adolescents [49, 60] and adults [36, 44].</li> <li>• The directionality of the association (positive vs. inverse association) varied depending on the indicator of kidney dysfunction assessed.</li> <li>• Two additional studies reported inconclusive [45] or no association [73] between water fluoride and kidney dysfunction.</li> </ul>
<b>Specificity</b>	Fluoride appears to play a role in the induction of a range of adverse health outcomes, and kidney dysfunction can be caused by a number of risk factors including exposure to toxic factors other than fluoride.
<b>Temporality</b>	Of the 4 studies that suggested a possible association, 3 were of cross-sectional design [36, 49, 60], whereby an inference of causality should not be inferred
<b>Biological gradient (exposure-response)</b>	<p>Of the two studies [49, 60] that reported results supporting a possible association between water fluoride levels and kidney dysfunction, both examined the exposure on a continuous scale.</p> <ul style="list-style-type: none"> <li>• One study reported a positive association for each unit increase in water fluoride (mg/L) with ALB (albumin), Cys-C (cystatin-C), OPN (osteopontin), TFF-3 (trefoil factor 3, significant), CLU (clusterin), KIM-1 (kidney injury molecule 1), and eGFR (estimated glomerular filtration rate, non-significant) [60].</li> <li>• The other study reported an inverse association for each 1mg/L increase in water fluoride with BUN (blood urea nitrogen, significant), eGFR, and ACR (urinary albumin to creatinine ratio, non-significant). Additionally, a positive association was observed with SUA (serum uric acid, non-significant) [49].</li> </ul>

**Biological  
plausibility**

- Histopathological changes in the kidney due to high fluoride exposure [44].
- Increased apoptosis and tubular epithelial damage, including necrosis, have also been observed among children with high fluoride exposures [49].
- Studies with adult rats have shown that chronic low-level fluoride exposure can lead to glomerular hypercellularity and mesangial cell proliferation, reduced kidney enzyme activity, interstitial nephritis, and renal tubule hypertrophy and hyperplasia [49].
- In experimental studies, exposure to fluoride has been associated with enzymatic inhibition, mitochondrial dysfunction (by the sirtuin 3 (SIRT3) pathway), oxidative stress generation and apoptosis induction (via activation of Bax expression and Bcl-2), especially in the S3 segment of the proximal tubules, which is considered the section most susceptible to fluoride toxicity [60]
- In animal models, these kidney toxicants have been shown to target predominantly the proximal tubule causing reactive oxygen species generation followed by endoplasmic reticulum stress and mitochondrial damage, culminating in cellular necrosis/apoptosis [73].
- In humans, chronic exposure to heavy metals and fluoride has been associated with kidney disease. However, most of these studies have been conducted in adults that are occupationally exposed and therefore, the effects of environmental exposure in children largely remains uninvestigated [73].
- Primary route of elimination is fluoride through kidneys and large number of experimental studies provide evidence that tubular area of kidneys is the most vulnerable to excess amounts of fluoride [112, 377].
- One of the plausible mechanisms of fluoride induced kidney damage particularly in renal tubules is by increasing lipid peroxidation and decreasing activities of antioxidant enzymes (oxidative stress) at cellular level or by activating apoptotic pathways leading to cell death and renal injury.

**Coherence**

- Coherence with previous evidence cannot be assessed based on the findings:
- No specific mechanisms were directly linked to fluoride and kidney dysfunction
  - Animal evidence was inconclusive/inadequate

**Experimental  
evidence**

- There has been no experimental evidence generated from human studies.
- Six experimental studies [112, 116, 149, 174, 232, 282] were identified that evaluated fluoride effects on kidney function at test concentrations required to achieve comparable blood fluoride levels in humans exposed to drinking water in Canada and are of lower risk of bias
- These studies investigated the impact of fluoride exposure in rodents (mice or rats) at different exposure durations (chronic or sub-chronic) given a range of

drinking water fluoride concentrations (ranged from 0.05 – 150 mg/L); specific outcomes measured include kidney dysfunction markers such as blood urea nitrogen (BUN) or creatinine (CRE) levels or histological analysis

- Three out of six studies found some histopathological changes in kidneys (such as proximal tubule injury) but none reported any significant changes in kidney dysfunction markers such as BUN or CRE at or above test concentrations relevant to humans (except one study found slight but significant increase in CRE levels after long term exposure at 20 ppm fluoride concentrations)

**Analogy** No suitable analogies identified

## Sex Hormones

The RSI search for the human evidence stream identified 2 cross-sectional studies [28, 42] that reported a positive association and one abstract with insufficient data [15] that reported a possible association between fluoride exposure and sex hormone alterations. Based on the available literature on humans to date, there is limited evidence for an association of levels of sex hormones and fluoride exposures relevant to current Canadian drinking water levels.

The search also identified multiple animal studies that reported a possible association between fluoride exposure and some proxy measures for male infertility, such as sperm quality and testicular damage; however, older multi-generational guideline rodent studies on reproductive toxicity indicated no association with number of pups delivered or with a fertility index. Moreover, the overall assessment of evidence from all streams using the Bradford Hill considerations was not strongly supportive of a causal association with fluoride in drinking water. Results from this assessment of the included studies are summarized in Section 6 of the Supplementary Material.

Table 21: Hill’s consideration of causality for fluoride and male sex hormones

<b>Criterion</b>	<b>Summary of Evidence</b>
<b>Strength of association</b>	<ul style="list-style-type: none"> <li>• One human study [28] of high-quality reported inverse association of fluoride in plasma and water with sex steroid hormones of total testosterone, where a possible biological gradient could be identified among all study groups except for male children. Similar disruptions of estradiol and sex hormone binding globulin (SHBG) could not be observed in U.S. children and adolescents.</li> <li>• Another human study [42] reported chronic fluoride exposure from drinking water is associated with significant differences of serum SHBG concentration among local male farmers in the high-exposure gp. (30.07 ± 28.32), compared to the low-exposure gp. (35.90 ± 28.58). The effect of fluoride exposure on androgen binding protein (ABP) levels was non-significant, and varied depending on estrogen receptor α gene (ESRα) gene polymorphisms.</li> <li>• All 11 experimental animal studies [109, 114, 115, 182, 183, 262, 263, 277, 284, 288, 313] identified in this review reported statistically significant changes in one or more outcomes related to male reproductive system dysfunction (male infertility) such as change in sperm quality or testosterone levels or histology of testis</li> <li>• These changes are observed at test concentrations relevant to humans i.e., concentrations required to achieve comparable serum fluoride levels in humans exposed to Canadian CWF levels.</li> <li>• These studies [109, 114, 115, 182, 183, 262, 263, 277, 284, 288, 313] included multiples species (rats and mice), dose ranges that relevant to current CWF levels, exposure pattern (i.e., continuous exposure through drinking water) and sufficient group size (i.e., 10 or more animals per treatment group).</li> </ul>
<b>Consistency</b>	<ul style="list-style-type: none"> <li>• The two identified human studies [28, 42] reported significant inverse associations with serum levels of different sex hormones in male and female adults, children and adolescents.</li> </ul>

	<ul style="list-style-type: none"> <li>• Drinking water fluoride studies in mice and rats over a range of study durations (chronic and sub-chronic) and doses (5 to &gt;20 ppm) that are relevant to current drinking water levels in Canada demonstrate a consistent association on the male reproductive outcomes such as sperm quality, histology of testis and testosterone levels (see experimental evidence table for male fertility in supplementary material 5).</li> </ul>
<b>Specificity</b>	Fluoride appears to play a role in the induction of a range of adverse health outcomes, and dysregulating male reproductive system/functions can be caused by a number of risk factors including exposure to toxic factors other than fluoride.
<b>Temporality</b>	<ul style="list-style-type: none"> <li>• The 2 human studies [28, 42] were cross-sectional design, and an inference of causality cannot be inferred.</li> <li>• In all experimental animal studies, the exposure (i.e., fluoride treatment) preceded the observation of outcomes (i.e., change in male reproductive outcomes)</li> </ul>
<b>Biological gradient (exposure-response)</b>	<ul style="list-style-type: none"> <li>• One human study [28] of high-quality reported inverse association of fluoride in plasma and water with sex steroid hormones of total testosterone, where a possible biological gradient could be identified among all study groups except for male children. Similar disruptions of estradiol and sex hormone binding globulin (SHBG) could not be observed in U.S. children and adolescents.</li> <li>• A second study by An and Colleagues [42] did not provide enough comparison groups to allow for a proper assessment of a biological gradient (high exposure vs. low exposure only).</li> <li>• All the included experimental animal studies reported significant changes in sperm quality with changes in fluoride levels in DW</li> <li>• Four studies found a linear dose response relationship between fluoride concentration in DW and one or more outcomes related to sperm quality (e.g., reduction in sperm motility, count or hyperactivity or increase in sperm abnormalities)</li> </ul>

**Biological plausibility**

- Animal experiments reported chronic fluoride exposure to damage Sertoli cells in, whether such damage can further alter serum ABP concentrations remains uncertain [42].
- In addition to ABP regulation by SHBG, ABP regulation in vivo has been reported to be regulated by androgen and FSH [42].
- Mounting evidence has indicated that both gene-gene and gene-environment interactions play important roles in regulating hormone levels. Males who carried different ESR $\alpha$  genotypes with the same fluoride exposure group had different serum ABP concentrations, suggesting that genetic polymorphisms also significantly affect serum ABP levels [42].
- One of the plausible mechanisms proposed for fluoride induced male reproductive toxicity is reducing gene/protein expression of NGF and other genes in MAPK pathways; nerve growth factor (NGF) plays a critical role in male reproductive system such as in sperm motility, inducing proliferation and differentiation of stem Leydig cells and production of testosterone [307].
- Another proposed mechanism is by induction of reactive oxygen species mediated endoplasmic reticulum (ER) stress pathway followed by apoptosis of Sertoli cells which play an important role in spermatogenesis [378]. Several studies linked toxicant induced ER stress pathways to impairment of male reproductive function such as changes in spermatogenesis, sperm function/ hyperactivation etc. [378].

**Coherence  
Experimental evidence**

- Evidence is predominantly based on animal stream
- There has been no experimental evidence generated from human studies.
  - Evidence is predominantly based on animal experimental studies

**Analogy**

## **IX. Derivation of a point of departure for moderate dental fluorosis**

### **Methodology**

#### **Summary of the US EPA (2010) dose-response analysis**

In its 2010 report <sup>[379]</sup> entitled *Fluoride: Dose-Response Analysis For Non-cancer Effects*, the US EPA performed a dose-response analysis on severe dental fluorosis as a function of fluoride in drinking water. The dose-response analysis was conducted using the dataset from Dean (1942) <sup>[380]</sup>. Five models were fit to the data (log-Probit model, Probit model, log logistic model, logistic model, and dichotomous Hill model) with the dichotomous Hill model as the preferred model based on its AIC value (see Table 4-2 from EPA (2010) <sup>[379]</sup>). The resulting benchmark dose (BMD) for 1% severe dental fluorosis was 2.43 mg/L, while the corresponding lower bound of the benchmark dose (BMDL) was found to be 2.18 mg/L. It should also be noted that USEPA <sup>[379]</sup> attempted to fit these models to data on moderate dental fluorosis; however, none of the models provided an acceptable model fit to derive benchmark dose using the selected analytic strategy.

#### **Identification of the key study**

As described above in the systematic review methods and results sections, a bibliographic search was conducted for all epidemiologic studies on fluoride in drinking water and dental fluorosis. The review was an update of the CADTH (2019) systematic review. However, in considering whether there existed a preferable study to Dean (1942), candidate key studies were considered from all studies published after 1942. The selection of a preferable key study involved several considerations: the study would have a low risk of bias based on its design and analytic methodology, there would be data adequate for a dose-response analysis of moderate dental fluorosis, the design of the study would not be entirely ecologic (that is, aggregate statistics) to allow for proper inference, other sources of fluoride would ideally be considered, the study would be based on a child or adolescent study population, ideally drinking water fluoride levels would be reflected in a range that includes levels below 0.7 ppm, the study size would be sufficiently large for dose-response modelling, and the study setting would offer natural parallels to a Canadian context. The team did not further consider studies

published before 2008 (as the US EPA had already reviewed these in detail). Risk of bias of studies published after 2008 were based on assessments conducted by Iheozor-Ejiofor et al [395], and CADTH (2019), and within the current RSI review.

Epidemiologic studies published to date were of variable risk of bias levels, particularly based on concerns for exposure assessment and potential confounding, among other issues. A major consideration was that other sources of fluoride (such as dental cleaning products and rinses) are common in more recent eras. This poses considerable uncertainty in dose-response modelling of the effects of fluoride in drinking water, as was also noted by the US EPA (2008). At the time of its review, the US EPA also preferred Dean (1942) because it used a standardized protocol to assess dental fluorosis, had a relatively large study size, and had a requirement for continuous residency of the children participating in the study.

As no candidate key studies were identified, for the reasons described above, Dean (1942) was still preferred for statistical modeling purposes.

## **Dataset**

Dean (1942) [380] was a cross-sectional study for 5824 children, in 22 cities across 10 states of the U.S. The children were 9-19 years old (grades 2-12). The design was comprised of a comparison of regions with varying water fluoride levels. Drinking water was the only route of exposure considered in the study. Dental fluorosis was measured using Dean's Index. Community fluoride concentrations were based on the Elvove (1933) method, derived from the mean of twelve-monthly samples.

The data used for the dose-response analysis is summarized in Table 33, which is generated by aggregating Table 33 from Dean (1942) [380] and sorting by the fluoride concentration levels in the drinking water supplies. The number of moderate (DFI=3) or severe (DFI=4) dental fluorosis cases for each community is calculated by combining proportions of moderate and severe dental fluorosis and multiplying by the number of study participants in each town. The US EPA (2010) [379] argued that data from the town of Bauxite, AR, was an outlier, with a confounding factor of the excessive amounts of alumina in the environment due to the aluminum mine and smelter in the region. Therefore, data for Bauxite (26 children at an exposure level of 14.1mg/L) is excluded from the present analysis.

Table 22: Fluoride concentration in drinking water supplies and number of cases of moderate/severe dental fluorosis (modified from Dean, 1942)

Town	State	Sample size	Age (Years)	F (mg/L)	Cases (Moderate + Severe)
Waukegan	IL	423	12-14	0	0
Michigan City	IN	236	12-14	0.1	0
Zanesville	OH	459	12-14	0.2	0
Lima	OH	454	12-14	0.3	0

<sup>1</sup> "Subject to possible correction to 4.2mg/L during susceptible period of age group examined." (Dean, 1942)

<sup>2</sup> Those observations are based on a single determination. Others are calculated as the average of samples across 12-month timeline.

<sup>3</sup> Corresponds to children in grades 4 to 6

<sup>4</sup> Corresponds to children in grades 3 to 12

<sup>5</sup> Corresponds to children in grades 2 to 12

## Bayesian vs. frequentist dose-response modelling

As mentioned in the US EPA (2010) report <sup>[379]</sup>, none of the models used in the dose-response modelling on the moderate and severe dental fluorosis provided acceptable fit to the data. For the current project, a Bayesian framework was employed for the benchmark dose estimation using the more recently available Benchmark BMD software (BBMD) developed by Shao and Shapiro (2018) (<https://benchmarkdose.com>)<sup>[381]</sup>. This approach would in principle provide improved model fit to a given dataset. Briefly, the Bayesian analysis calculates the posterior probability for parameter set  $\theta$  given data (i.e.,  $p(\theta|\text{Data})$ ) as

$$p(\theta|\text{Data}) \propto \pi(\theta)L(\text{Data}|\theta),$$

where  $\pi(\theta)$  denotes the prior distribution for  $\theta$ ,  $L(\text{Data}|\theta)$  represents the likelihood function. In particular, since the data is dichotomous (i.e., “success” if a study participant exhibits moderate or severe dental fluorosis, or “failure” otherwise), the likelihood function can be described using binomial distribution.

$$L(\text{Data}|\theta) = \prod_{i=1}^I \binom{n_i}{y_i} p(d_i|\theta)^{y_i} [1 - p(d_i|\theta)]^{n_i - y_i},$$

where  $n_i$  represents the number of participants in each exposure group, and  $y_i$  corresponds to number of participants developing moderate or severe dental fluorosis in  $i^{\text{th}}$  exposure group, and  $p(d_i|\theta)$  is the probability of developing moderate or severe dental fluorosis given exposure concentration at  $i^{\text{th}}$  group. For all analyses, to derive a BMD and POD to protect against moderate dental fluorosis, a DFI cutoff of 3+ was used for modelling (i.e., a combination of moderate (DFI=3) and severe (DFI=4) categories, as described in Dean (1942).

There are a number of plausible dose-response model that can be used for the analysis. In particular, the BBMD software provides eight models available for the dose-response analysis to fit dichotomous data:

- Quantal linear model
- Probit model
- Logistic model
- Weibull model
- Multistage (2<sup>nd</sup> order) model

- Log Logistic model
- Log Probit model
- Dichotomous Hill model

All eight models provided by the BBMD software were used for the dose-response analysis; however, only log-logistic, log-Probit, and dichotomous Hill models provided convergence and adequate fit for the main analysis. These three models, as well as the prior distributions for corresponding model parameters are shown below.

### Log-logistic model

$$f(d) = a + \frac{1 - a}{1 + e^{-(c+b \times \log(d))}},$$

where the prior distributions for the parameters are given by:  $a \sim \text{Uniform}(0, 1)$ ;  $b \sim \text{Uniform}(1, 15)$ ; and  $c \sim \text{Uniform}(-5, 15)$ .

### Log-Probit model

$$f(d) = a + (1 - a) \times \Phi(c + b \times \log(d)),$$

where the prior distributions for the parameters are given by:  $a \sim \text{Uniform}(0, 1)$ ;  $b \sim \text{Uniform}(1, 15)$ ; and  $c \sim \text{Uniform}(-5, 15)$ .

### Dichotomous Hill model

$$f(d) = a \times g + \frac{a(1 - g)}{a + e^{-(c+d \times \log(d))}},$$

where the prior distributions for the parameters are given by:  $a \sim \text{Uniform}(0, 1)$ ;  $b \sim \text{Uniform}(1, 15)$ ;  $c \sim \text{Uniform}(-5, 15)$ ; and  $g \sim \text{Uniform}(0, 1)$ .

For the prior distributions for all parameters, the uniform distribution with the default lower and upper bounds are used. These default values were chosen based on the biological

considerations (Shao and Shapiro, 2018) <sup>[381]</sup>. See section 2 of the supplemental material from Shao and Shapiro (2018) <sup>[381]</sup> for the details of the remaining models.

### **Benchmark-dose modelling of added and extra risks**

The objective of the dose-response analysis conducted in this section is to derive a point-of-departure (POD) using the BMD and the BMDL. The added-risk and extra-risk-based BMDs, for a prespecified benchmark response (BMR), can be defined as

$$\text{BMD}_{\text{ad}} = \{d: f(d) - f(0) = \text{BMR}\},$$

and

$$\text{BMD}_{\text{ex}} = \left\{d: \frac{f(d) - f(0)}{1 - f(0)} = \text{BMR}\right\},$$

where  $f(d)$  and  $f(0)$  correspond to the risk of developing moderate or severe dental fluorosis at exposure levels  $d$  and 0, respectively.

### **Choice of benchmark response**

Derivation of BMD and BMDL estimates were based on the extra-risk BMR of 1%, 5%, and 10%, given that extra-risk based BMR would always produce an estimate less than or equal to the BMD based on added risk.

### **Adequacy of model fit**

As in classical (i.e., frequentist) statistics, the model fit to the data can be checked for adequacy in the Bayesian analysis. One such measure is called the posterior predictive p-value (PPP). The PPP indicates the discrepancy between the observed data and the plausibility of generating the observed data based on the posterior predictive distribution. If the model's PPP value is between 0.05 and 0.95, the model's fit is thought to be adequate. For a more detailed explanation of the PPP, see Gelman (2013) <sup>[382]</sup>.

## Model selection and model averaging

When there is more than one plausible model to describe the dose-response relationship, there would be more than one BMD estimate derived. There are two ways to determine a single “best” BMD estimate from a set of BMDs. One way is to choose the BMD from the most plausible model (model selection), and another way is to calculate the weighted average of the BMD estimates (model averaging). Either way, such determination requires the use of posterior model weights.

First, assume that equal prior model weights are assigned to each of candidate model, as there is no reason to believe one model is more plausible than others. Consequently, the model weight <sup>[383]</sup> for the  $j^{\text{th}}$  model can be calculated as

$$\hat{m}_j = \exp\left(\hat{l}_j - \frac{d_j}{2} \log(n)\right),$$

where  $\hat{l}_j$  denotes the estimated loglikelihood value,  $d_j$  represents the number of parameters used in  $j^{\text{th}}$  model, with sample size represented by  $n$ . Therefore, using equal prior model weights, the posterior model weight for each of the model included in model selection/averaging can be calculated as

$$\hat{p}m_j = \frac{\hat{m}_j}{\sum_{t=1}^T \hat{m}_t},$$

and therefore, the BMD estimate for model selection is given by

$$\widehat{\text{BMD}}_{MS} = \underset{\hat{p}m_j}{\text{argmax}} \widehat{\text{BMD}}_j.$$

Similarly, the BMD estimate for the model averaging is given by

$$\widehat{\text{BMD}}_{MA} = \sum_{t=1}^T \hat{p}m_t \times \widehat{\text{BMD}}_j.$$

## Results

### NOAEL and LOAEL

Although the purpose of this section is to determine the POD based on BMD, it is worthwhile noting that the no observed adverse effect level (NOAEL) and lowest observed adverse effect

level (LOAEL) for the moderate or severe dental fluorosis are 1.3 mg/L and 1.8 mg/L, respectively. The LOAEL corresponds to a 1.2% positivity rate in the study participants from Elmhurst, IL (when all communities in Dean (1942) are sorted by fluoride concentration, the lowest concentration at which moderate dental fluorosis manifests is within the Elmhurst community, which had 1.8 ppm F concentration).

## BMD estimates based on individual models

### Dose-response analysis using log logistic model

Figure 4 shows the estimated dose-response curve using log logistic model. With the PPP value of 0.453, there is no reason to believe the inadequacy of the model fit. The estimated BMD and BMDL based on extra-risk based BMR of 1%, 5%, and 10% are presented in Table 23. When the BMR is set to 1%, the BMD and BMDL estimates are 1.45 mg/L and 1.35 mg/L, respectively. The estimated model weight for log logistic model is less than 0.001%, indicating that, of the three models used in this analysis, log logistic model has the lowest loglikelihood.

It should also be noted that, as the estimated background risk of developing moderate or severe dental fluorosis is  $2.4 \times 10^{-4}$  (Table 24), the added-risk based BMD and BMDL estimates would be the same as those shown in Table 23. The parameter estimates given in Table 24 uses the normalized exposure levels. In short, exposure levels in all data sets are normalized to the scale between 0 to 1 by dividing the exposure level  $d$  by the maximum exposure level ( $8.0\text{mg/L}$ ) from the study.

Figure 4: Estimated dose-response curve using log logistic model (orange line), with 90% confidence interval shown in light blue shade.

(Green dots represent the observed data while the vertical bars denote the 90% confidence interval about the observation.)

Table 23: Estimated BMD and BMDL values based on log logistic model. The extra-risk based BMR are used.

BMR	Log Logistic Model	
	BMD (mg/L)	BMDL (mg/L)
1%	1.45	1.35
5%	2.11	2.01
10%	2.50	2.41

Parameter	Log Logistic model		
	Mean	SE(Mean)	Standard Deviation
<i>a</i>	$2.4 \times 10^{-4}$	$2.0 \times 10^{-6}$	$2.4 \times 10^{-4}$
<i>b</i>	4.38	$2.1 \times 10^{-3}$	0.2
<i>c</i>	2.9	$1.9 \times 10^{-3}$	0.18
<i>lp</i>	-737.6	0.01	1.27

### Dose-response analysis using log Probit model

Figure 5 shows the estimated dose-response curve using log logistic model. With the PPP value of 0.396, there is no reason to believe the inadequacy of the model fit. Table 23 summarizes the estimated BMD and BMDL based on extra-risk based BMR of 1%, 5%, and 10%. When the BMR is set to 1%, the BMD and BMDL estimates are 1.58 mg/L and 1.49 mg/L, respectively. The estimated model weight for log logistic model is 0.046%, implying that log Probit model is a more plausible underlying model than the log logistic model for

describing dose-response relationship between fluoride concentration in drinking water and development of moderate or severe dental fluorosis.

Similar to the log logistic model, as the estimated background risk of developing moderate or severe dental fluorosis is  $2.4 \times 10^{-4}$  (Table 25), the added-risk based BMD and BMDL estimates would be the same as those shown in

Table 26. Note also that the parameter estimates given in Table 25 uses the normalized exposure levels.

### Dose-response analysis using dichotomous Hill model

Figure 6 shows the estimated dose-response curve using log logistic model. With the PPP value of 0.452, there is no reason to believe the inadequacy of the model fit. As shown in Figure 4, the dichotomous Hill model plateaus at 78% response rate, meaning that Hill model assumes that even as fluoride concentration increase infinitely, only about 78% of population would develop either moderate or severe dental fluorosis. The estimated BMD and BMDL based on extra-risk based BMR of 1%, 5%, and 10% are presented in Table 27. When the BMR is set to 1%, the BMD and BMDL estimates are 1.66 mg/L and 1.56 mg/L, respectively, which are slightly larger than those based on the log logistic and the log Probit model. When considering the model averaging results, the estimates were heavily weighted toward those of the Hill model (estimated model weight of 99.95%).

The background rate for the Hill model is given by  $(a \times g)$ . From Table 28, we obtain that  $a \times g = 2.5 \times 10^{-4}$ , and therefore the added-risk based BMD and BMDL estimates for the Hill model are identical to those presented in Table 27. Note also that the parameter estimates given in Table 28 uses the normalized exposure levels.

Figure 6: Estimated dose-response curve using dichotomous Hill model (orange line), with 90% confidence interval shown in light blue shade.

*(Green dots represent the observed data while the vertical bars denote the 90% confidence interval about the observation.)*

Table 27: Estimated BMD and BMDL values based on dichotomous Hill model. The extra-risk based BMR are used.

BMR	Dichotomous Hill Model	
	BMD (mg/L)	BMDL (mg/L)

<b>g</b>	$3.2 \times 10^{-4}$	$2.5 \times 10^{-6}$	$3.2 \times 10^{-4}$
<b>lp</b>	-732.5	0.01	1.29

### BMD estimates using model averaging

In the previous section, based on an estimated model weights and fit statistics, the Hill model may be the single most plausible model to describe the dose-response relationship based on the data from Dean (1942) [380]. Since there always is an uncertainty about which model is the “true” model, it may be beneficial to adjust the BMD and BMDL estimates by taking the weighted average of the BMD estimates from different models. As shown in Table 29, BMD and BMDL estimates based on model averaging is identical to those of Hill model. This is because the model weight for the Hill model is 99.95%. Therefore, whether model averaging or model selection is used, the BMD and BMDL estimates corresponding to 1% BMR would be 1.66 mg/L and 1.56 mg/L, respectively.

Table 29: Estimated BMD and BMDL values by model averaging. The extra-risk based BMR are used.

BMR	Model Averaging	
	BMD (mg/L)	BMDL (mg/L)
<b>1%</b>	1.66	1.56
<b>5%</b>	2.22	2.13
<b>10%</b>	2.53	2.46

## Sensitivity analysis

### Effect of correction in exposure

As stated in the footnote on Table 22, Dean (1942) <sup>[380]</sup> indicated the exposure level in Amarillo, TX, may be subject to a possible correction to 4.2 mg/L (instead of 3.9 mg/L) “during susceptible period of age group examined”. Although the age group of study participants from Amarillo does not seem to differ greatly from children from other communities, a sensitivity analysis was based on the dose-response analysis with a modified fluoride concentration for the Amarillo subjects.

The BMD and BMDL estimates under log logistic, log Probit, and Hill models, as well as from model averaging are provided in Table 30. As expected, these estimates are very similar to those from the original analysis (Table 23, Table 25, Table 27, and Table 29). In particular, BMD and BMDL estimates for 1% extra risk based on model averaging are 1.63 mg/L and 1.52 mg/L, respectively.

Table 30: BMD and BMDL estimates under various models. The exposure level for Amarillo, TX, has been modified to 4.2 mg/L for possible susceptible period of age group examined, as noted by Dean (1942).

BMR	Log logistic Model		Log Probit Model		Dichotomous Hill Model		Model Average	
	BMD	BMDL	BMD	BMDL	BMD	BMDL	BMD	BMDL
1%	1.63	1.52	1.44	1.34	1.58	1.49	1.63	1.52
5%	2.21	2.12	2.13	2.04	2.12	2.03	2.22	2.12
10%	2.55	2.46	2.54	2.45	2.48	2.39	2.55	2.46

### Effect of higher concentration groups

The Hill model provided the best fit in the main analysis. This may be due to the extra parameter in the Hill model that allows for the model to plateau before reaching a 100% incidence rate. To investigate the effect of the plateauing effect on the estimation of BMD, two additional analyses were considered, where the highest concentration group (i.e., Ankeny, IA at 8.0 mg/L) and two highest concentration groups (i.e., Ankeny, IA, and Chetopa, KS at 7.6

mg/L) are removed. The BMD estimates based on these additional analyses are presented in Table 31 and Table 32. When only the highest concentration group is excluded, the resulting model average BMD and BMDL estimates are nearly identical to those found in the original analysis (1.68 mg/L vs. 1.66 mg/L for BMD, and 1.57 mg/L vs. 1.56 mg/L for BMDL for 1% BMR). When the two highest exposure groups are excluded, the model average BMD estimates are slightly increased at 1.72mg/L for 1% BMR. Although the BMD estimates are mostly unaffected by the plateauing effect, when both Ankeny and Chetopa subjects were excluded from the analysis, the log Probit model became the dominant dose-response model (with the model weight of 91.2%). This indicates that the model fit may be heavily influenced by the plateauing effect (i.e., whether incidence rate will become 100% as exposure increase or not), and therefore it would be preferable to use the BMD and BMDL estimates from model averaging, rather than using only the most plausible model.

Table 31: BMD and BMDL estimates under various models. The highest exposure group (Ankeny, IA) is excluded from this dose-response analysis.

BMR	Log logistic Model		Log Probit Model		Dichotomous Hill Model		Model Average	
	BMD	BMDL	BMD	BMDL	BMD	BMDL	BMD	BMDL
1%	1.45	1.35	1.58	1.49	1.68	1.57	1.68	1.57
5%	2.11	2.02	2.1	2.02	2.22	2.13	2.22	2.13
10%	2.50	2.42	2.45	2.37	2.53	2.45	2.53	2.45

Table 32: BMD and BMDL estimates under various models. The two highest exposure groups (Ankeny, IA, and Chetopa, KS) are excluded from this dose-response analysis.

BMR	Log logistic Model		Log Probit Model		Dichotomous Hill Model		Model Average	
	BMD	BMDL	BMD	BMDL	BMD	BMDL	BMD	BMDL
1%	1.60	1.50	1.72	1.63	1.63	1.52	1.72	1.59
5%	2.21	2.12	2.2	2.11	2.22	2.13	2.2	2.11
10%	2.57	2.48	2.5	2.42	2.55	2.47	2.51	2.43

## Conclusion

The dose-response analysis using data from Dean (1942) [380] was performed to investigate the relationship between the fluoride concentration in drinking water and the development of moderate or severe dental fluorosis. The model average benchmark dose for 1% extra-risk and corresponding BMDL were determined to be 1.66 mg/L, and 1.56 mg/L, respectively. These values are slightly less than the LOAEL (1.8 mg/L), which had the positivity rate of 1.2% in the study population. Although three models were used to derive the model average BMD, the Hill model was the dominant model with a 99.95% model weight.

There were some uncertainties in some of the collected data. For example, Dean (1942) suggested that a potential correction for the exposure level for the town of Amarillo may be needed. A sensitivity analysis with modified data suggested that the 1% BMD and BMDL are slightly decreased at 1.62mg/L and 1.53mg/L, respectively. Another sensitivity analysis was performed to investigate the impact of plateauing effect on the BMD estimates. When two of the highest exposure groups were excluded, the BMD and BDML estimates increased slightly, to 1.72 mg/L and 1.59 mg/L. Although the BMD estimates were stable, removal of highest concentration groups led to change in the dominant model (log Probit model had model weight of 91.2%), indicating that BMD estimation should be based on model averaging rather than model selection.

## X. Derivation of points of departure for other candidate endpoints

The following Table 33 presents a selection of international HBV and MAC for fluoride in drinking water. These guidelines were based on considerations of the beneficial prevention of dental caries and the protection against dental fluorosis (as the most sensitive endpoint). The selection of candidate endpoints in the current RSI report and the derivation of points of departure in a subsequent section were based on a review of all other health endpoints, excluding dental fluorosis.

Table 33: HBV and MAC values reported by different authoritative agencies

Country / Organization	Reference Values	Source
WHO	<p>“The guideline value for fluoride in drinking-water is 1.5 mg/L, based on increasing risk of dental fluorosis at higher concentrations and that progressively higher levels lead to increasing risks of skeletal fluorosis. This value is higher than that recommended for artificial fluoridation of water supplies for prevention of dental caries, which is usually 0.5–1.0 mg/L.” (p. 3)</p>	WHO 2019 <sup>[384]</sup>
Canada	<p>“... the optimal concentration of fluoride in drinking water for dental health has been determined to be 0.7 mg/L for communities who wish to fluoridate.” (p. 2)</p> <p>“The maximum acceptable concentration (MAC) for fluoride in drinking water is 1.5 mg/L ... Mild and very mild dental fluorosis are not considered to be adverse effects, whereas moderate dental fluorosis is found to be an adverse effect, based on its potential cosmetic concern, and is used as the endpoint of concern in the risk assessment used to establish the Maximum Acceptable Concentration.” (p. 1)</p> <p>“Health Canada has calculated a health-based value of 0.9 mg/L for fluoride in drinking water, which is deemed protective against any potential adverse health effect from fluoride.” (p. 64)</p>	Health Canada 2010 <sup>[1]</sup> .
USA	<p>“For community water systems that add fluoride to their water, PHS recommends a fluoride concentration of 0.7 mg/L (parts per million [ppm]) to maintain caries prevention benefits and reduce the risk of dental fluorosis.” (p. 319)</p>	U.S. Department of Health and Human Services 2015 <sup>[385]</sup>
	<p>“The current enforceable drinking water standard for fluoride is 4.0 mg/L. This is the maximum amount that is allowed in water from public water systems. It is set to meet the current public health goal for protection against increased risk of crippling skeletal fluorosis, a condition characterized by pain and tenderness of the major joints.” (p. 2)</p> <p>“EPA also has a non-enforceable secondary standard for fluoride of 2.0 mg/L, which is recommended to protect children against the tooth discoloration and/or pitting that can be caused by excess fluoride exposures during the formative period prior to eruption of the teeth. Although water systems are not required to comply with secondary standards, for fluoride, EPA does require that systems notify customers if the average water levels exceed the secondary standard.” (p. 2 – 3)</p>	US Environmental Protection Agency 2011 <sup>[386]</sup>

Country / Organization	Reference Values	Source
Australia	<p>“Based on health considerations, the concentration of fluoride in drinking water should not exceed 1.5 mg/L.” (p. 668)</p> <p>“The guideline value of 1.5 mg/L has been set to protect children from the risk of dental fluorosis.” (p. 669)</p>	<p><b>National Health and Medical Research Council, Australia 2021</b> [10]</p>
	<p>“NHMRC supports Australian states and territories fluoridating their drinking water supplies within the range of 0.6 to 1.1 mg/L. This range is aimed at reducing tooth decay, while avoiding any occurrence of dental fluorosis of aesthetic concern. In each Australian state or territory, the government health authority determines the appropriate operational levels within the range of 0.6 to 1.1 mg/L.” (p. 1)</p>	<p><b>National Health and Medical Research Council, Australia 2017</b> [10]</p>
Ireland	<p>“Community water fluoridation at a level of 1 ppm began in Ireland in 1964 as a measure to prevent dental caries. A major review of Ireland’s water fluoridation policy in 2002 showed an increasing occurrence of dental fluorosis. As a result, in 2007, the fluoride level in drinking water in Ireland was lowered to a range of 0.6 to 0.8 ppm, with a target of 0.7 ppm. This remains the target and range applied in Ireland today.” (p. 6)</p>	<p><b>Sutton et al. 2015</b> [387]</p>
	<p>“In Europe, the maximum level of fluoride currently allowed in drinking water is 1.5 parts per million (ppm) (2). However, in Ireland, the 1960 Health (Fluoridation of Water Supplies) Act restricts the maximum level of fluoride to only 1ppm and this supersedes the European maximum limit.” (p. 18)</p>	<p><b>Food Safety Authority of Ireland 2006</b> [388]</p>
New Zealand	<p>“The NZMoH [New Zealand Ministry of Health] recommends that, for oral health reasons, the level of fluoride in drinking water in New Zealand should be between 0.7 and 1.0 mg/L. Based on WHO advice, the maximum acceptable value for fluoride in drinking water is 1.5 mg/L to prevent any known adverse health effects (dental or skeletal fluorosis).” (p. 22)</p>	<p><b>Royal Society of New Zealand 2014</b> [389]</p>

## Cognition, IQ

The body of evidence considered in the current RSI review suggests a positive association of reduced IQ scores for children and fluoride exposures relevant to current Canadian drinking

water levels. Using the 2022 NTP dose-response mean-effects meta-analysis <sup>[421]</sup> of 29 human epidemiologic studies with aggregate-level exposure measurement, the linear dose-response model resulted in a change (a reduction) in IQ of -0.15 (standardized mean difference (SMD), 95% CL: -0.20, -0.11) between the drinking water fluoride exposed group and the reference group within each study. Restricting the dose-response meta-analysis to those studies that included an exposed (non-reference) group with mean fluoride concentrations below 1.5 mg/L (7 studies contributed 7 observations to the dose-response estimate) resulted in an estimate of the change in IQ of 0.05 (standardized mean difference, 95% CL: -0.36, 0.45) between the exposed group and the reference group using a linear model. This latter result could be used as evidence to reconsider the HBV for fluoride in drinking water in Canada; however, the estimate was based on largely cross-sectional studies with high risk of bias, including lack of adjustment for effects of other contaminants, such as arsenic and lead. The 2022 NTP draft also includes a mean effects meta-analysis <sup>[421]</sup>, with studies that reported sex-stratified results (14 studies of boys, 13 studies of girls) with these subgroup analyses resulting in IQ changes of (SMD) -0.62 (95% CI: -0.81, -0.42) in boys and -0.53 (95% CI: -0.72, -0.34) in girls. The 2022 NTP draft includes a regression slopes meta-analysis of epidemiologic studies with individual-level fluoride exposure measures (including several cohort studies) with an estimated -4.77 IQ point change for a 1-mg/L increase in water fluoride ( $\beta = -4.77$ ; 95% CI: -9.09, -0.45) and -1.81 (-2.80, -0.81) for urinary fluoride.

Benchmark dose (BMD) modelling results have been recently published, based on high-quality birth cohort data. Grandjean and Colleagues <sup>[390]</sup> conducted a BMD analysis using the pooled MIREC and ELEMENT cohorts, with assessment of maternal urinary fluoride levels. The MIREC Canadian cohort (Maternal–Infant Research on Environmental Chemicals) was the basis of previous assessments of prenatal fluoride exposure and childhood IQ (Till et al. (2020) <sup>[40]</sup> and Green et al. (2019) <sup>[326]</sup>) and the ELEMENT longitudinal birth cohort (Early Life Exposures in Mexico to Environmental Toxicants) was used to assess maternal and fetal fluoride exposure and childhood IQ in a Mexican population (Bashash et al. (2017)) <sup>[71]</sup>. The combined cohort represents high quality evidence partly based on a Canadian population, conducted within a context relevant to Canadian drinking water fluoride exposure levels. Both studies included prospective data collection, with prenatal exposure assessment (maternal urine collection over successive trimesters) and follow-up during the early life of the infants

and children. In risk of bias assessments conducted by NTP, the earlier publications by Green et al., Till et al., and Bashash et al. were assessed at low risk of bias due to unlikely concerns from measurement error on cognition and urine F concentration, selection of study samples, and confounding adjustment from known factors [These assessments are relevant to the publication by Grandjean et al., which used the same data sources]. Exposure coverage in the cohort reflects (urinary) fluoride levels below the current health-based value of 0.9 mg/L for fluoride in drinking water (with Grandjean reporting the mean urinary fluoride concentration [creatinine-adjusted] among pregnant women was 0.89 mg/L in Mexico City and 0.84 mg/L in Canada). Regression modelling by Grandjean et al. (2022) includes adjustment for critical confounders, including other chemical neurotoxicants in drinking water and socioeconomic impacts that would affect cognitive and mental health development. Adjustment included arsenic and lead exposures, as well as non-chemical determinants (gestational age, age at measurement, maternal education, race/ethnicity, child sex, parity, second-hand smoke, city, and quality of home environment [emotional support; cognitive stimulation]). Stratified and models with interaction terms were included to the relationship between sex and urinary-fluoride exposure. In the BMD modelling, various regression models (linear, quadratic, segmented) were used to estimate the benchmark concentration for a benchmark response of a 1-point reduction in IQ. Model fits were similar but resulted in widely varying estimated benchmark concentrations, with some models for girls not converging. At present, mode and mechanism of action information is insufficient to establish a preference for the linear or nonlinear models considered by Grandjean and Colleagues <sup>[390]</sup>. Based on a benchmark response (BMR) of 1 IQ point and using the linear model results, the benchmark concentration (BMC) for maternal urinary fluoride (MUF) was 0.312 mg MUF/L, and the one-sided lower limit of the BMC (the BMCL) was 0.192 mg MUF/L) when pooling General Cognitive Index (GCI) scores for the youngest children of both sexes in both cohorts. In sex-stratified results, estimated benchmark concentrations were lower in boys than in girls. Results varied in the two cohorts and by age at measurement – but when pooled for the youngest aged children, the derived BMCL from the linear model for boys was 0.125 MUF/L and for girls was 0.315 MUF/L.

To derive a potential *BMCL for fluoride in drinking water* based on the maternal urinary results from the pooled analysis of the MIREC and ELEMENT cohorts conducted by Grandjean and Colleagues <sup>[390]</sup> requires a conversion based on the following assumptions:

- Because of the uncertainty as to the shape of the dose-response curve at low concentrations of drinking water, the more stringent linear model, rather than the squared or break-point models considered by Grandjean and Colleagues <sup>[390]</sup>, was selected in order that the BMCL not be overestimated.
- For a BMR of 1 IQ point, the  $BMCL_{MUF}$  was 0.192 mg MUF/L, based on the linear model results from Grandjean et al. for the pooled cohorts at younger ages
- Daily drinking water intake is 1.53 L/day (Health Canada default value).
- 24-hour fraction of fluoride excretion in adults is 0.75 (from Villa et al., 2004). This fractional urinary fluoride excretion (FUFE) is the ratio of fluoride excreted and fluoride ingested,  $FUFE = F_{excr}/F_{ing}$ ,
- $F_{excr}$  is a product of urinary volume (over 24h) and the urinary fluoride concentration. A normal range of 24-hour urine volume is 800 to 1,200 mL,<sup>34</sup> with 2 L of fluid intake per day. Given the mid-value of 1.4 L of urine volume per 2 L of fluid intake, and assuming linearity, the 24-hour urine volume for Canadians (with 1.53 L intake) would be 1.07 L.
- The susceptible population was young school-aged children, with the critical window of exposure being during prenatal periods and thus based on maternal intake.

Under these assumptions, the amount of fluoride ingested per day corresponding to the  $BMCL_{MUF}$  is:

$$\begin{aligned}
 F_{ing} &= [BMCL_{MUF} \times 24\text{-hour urine volume}] / FUFE \\
 &= [0.192 \text{ mg/L} \times 1.07 \text{ L/d}] / 0.75 \\
 &= 0.274 \text{ mg/day}
 \end{aligned}$$

And the BMCL for fluoride in drinking water is then calculated as:

$$\begin{aligned}
 BMCL_{DW} &= F_{ing} / \text{water intake} \\
 &= (0.274 \text{ mg/day}) / (1.53 \text{ L/day}) \\
 &= 0.179 \text{ mg F/L}^{35}
 \end{aligned}$$

<sup>34</sup> [Urine 24-hour volume Information | Mount Sinai - New York](#)

<sup>35</sup> The derivation of the drinking water BMCL, based on Grandjean and Colleagues 390. Grandjean, P., et al., *A Benchmark Dose Analysis for Maternal Pregnancy Urine-Fluoride and IQ in Children*. *Risk Anal*, 2022. **42**(3): p. 439-449. results, assumes that all fluoride ingested is via drinking water. Villa et al. (2004) reported for their participants, about 75% of  $F_{ing}$  could be attributed to drinking fluids (but food, drinks, and toothpaste were all

Grandjean and Colleagues <sup>[390]</sup> fit different linear and non-linear models, which resulted in lower bounds of benchmark concentrations which differed by more than 9-fold (when converted to drinking water concentration, with the method described above, the variously derived BMCLs ranged from 0.077 mg F/L to 0.753 mg F/L drinking water).

The point of departure of 0.179 mg F/L from the combined high-quality cohorts stands in contrast to the 2022 draft NTP report conclusions that evidence for fluoride effects on cognitive function in children is less consistent below 1.5 mg F/L. In choosing between the BMCL of 0.179 mg F/L based on the more stringent model fit to the MIREC and ELEMENT cohorts by Grandjean and Colleagues <sup>[390]</sup>, and a weight of evidence conclusion that evidence for neurological effects of fluoride in children below concentrations of 1.5 mg F/L was less consistent, consideration was also given to the quality of evidence. While the BMCL derived from the cohort data suggests a much lower POD than 1.5 mg/L, the overall body of evidence suggests significant uncertainty in any low exposure-range derivation with current evidence. At this point in time, 1.5 mg/L may be considered as a provisional point of departure for establishing an HBV for fluoride in Canadian drinking water based on protection against neurocognitive effects in children. This POD should be reviewed as additional data accumulates on the biological mechanisms by which fluoride impacts cognitive function, providing additional insights into the shape of the exposure-response curve at lower concentrations.

## **Thyroid dysfunction**

The RSI review and weighing of evidence under Bradford Hill considerations provided reasonable credibility from generally low to acceptable risk of bias – albeit cross-sectional – human epidemiologic studies to suggest a possible association of fluoride exposure in Canadian drinking water contexts and effects on thyroid dysfunction. No study was considered adequate to derive a point of departure. In considering the animal stream of evidence, only 2 low risk of bias studies with dose-response information were considered relevant <sup>[187, 208]</sup>. Out of these 2 rat chronic studies, one study did not find a change in thyroid

---

controlled in the study, and the study was conducted in Chile, which may be less applicable to a Canadian population).

hormone levels (T3, T4, or TSH) at the highest test concentrations (20 ppm), and the other study did not consistently demonstrate significant change across time points. Overall, these studies were considered insufficient for derivation of a point of departure for thyroid-related effects in humans.

No point of departure was derived.

### **Kidney dysfunction**

Epidemiologic human studies were broadly consistent on supporting a possible association of fluoride exposure in Canadian contexts and effects on kidney dysfunction, with weighing of evidence under Bradford-Hill considerations supportive of the association being possibly causal. However, all human studies were cross-sectional in design and were not considered adequate for a derivation of a point of departure. Although a few low risk-of-bias animal studies demonstrated selective histopathological changes in the kidney (such as proximal tubule injury, but without any significant changes in kidney dysfunction markers such as BUN or CRE), the studies were of insufficient duration (mostly sub-chronic), or small group size (less than 10 per sex per group), or considered inadequate to derive a point of departure for kidney dysfunction in humans. Overall, these studies were considered insufficient for derivation of a point of departure for kidney dysfunction in humans.

No point of departure was derived.

### **Sex hormone dysfunction**

In the human stream of evidence, 2 low risk of bias cross-sectional studies were identified. While considered low risk of bias in the OHAT scoring, cross-sectional studies were not considered adequate for consideration in deriving a point of departure. Recent animal studies identified in the RSI review suggested an association with proxy measures of male infertility such as sperm quality and testicular damage; however, older multi-generational guideline rodent studies on reproductive toxicity indicated no association with number of pups delivered or with a fertility index. Weighing of evidence under Bradford Hill considerations was not strongly supportive of a causal association with fluoride in drinking water. Overall, these studies were considered insufficient for derivation of a point of departure for sex hormone derangement effects in humans.

No point of departure was derived.

## **XI. Considerations for selection of most appropriate endpoint and a point of departure**

The current RSI review encompassed a thorough, multi-pronged examination of the effects of exposure to fluoride in drinking water on adverse health outcomes. The ultimate goal of this review was to provide evidence with which Health Canada could consider updating the current MAC for fluoride in drinking water. To identify the most sensitive and most appropriate endpoint of concern, the review included considerations for deriving an appropriate POD, for which there is good quality data demonstrating a well-defined exposure-response relationship. This examination involved the identification and assessment of quality of all new evidence from human, animal, and in vitro studies that had been published after the release of two CADTH reports in 2019 <sup>[2, 3]</sup>, the NTP report in 2016 <sup>[4]</sup>, and the Health Canada report in 2010 <sup>[1]</sup>. In synthesizing this evidence, the quality and potential risk of bias of individual studies was taken into consideration. The combined evidence generated from these different streams was then examined via the Bradford Hill considerations <sup>[8]</sup> for identification of credible causal adverse effects due to fluoride exposure.

In reconsidering an update of the MAC for fluoride in drinking water for Canadians, the HBV based on dental fluorosis was revisited using the newly published scientific evidence and results from new modelling of the Dean (1942) data on dental fluorosis. Moderate dental fluorosis was selected as the level of fluorosis of concern by Health Canada. Furthermore, based on weight of evidence, four new endpoints were considered as credible candidates for most sensitive endpoint. While effects on sex hormones, thyroid dysfunction, and kidney dysfunction are potential adverse effects of fluoride exposure through drinking water, with enough supporting evidence to warrant concern, no points of departure were derived because of inadequate data sources to conduct dose-response modelling.

The overall evidence identified to date strongly suggests that fluoride can affect cognitive outcomes in children (specifically, reduction in IQ scores), at levels close to those currently seen in Canadian drinking water.

Hence, the selection of the most sensitive endpoint requires a comparison of the point of departure for moderate dental fluorosis and the point of departure for IQ effects. For both endpoints, the vulnerable population is young, school-aged children, though critical periods of exposure likely differ (prenatal vs. early life).

First, the POD for moderate/ severe dental fluorosis was derived in the current report as:

- 1.56 mg/L for a BMR of 1%, 2.13 mg/L for a BMR of 5%, and 2.46 mg/L for a BMR of 10%

While data on moderate dental fluorosis could not be fit at the time of the US EPA report (2010) using a classical approach, the current values were estimated using Bayesian model averaging to derive the extra risk-based BMDL across three alternative dose-response models using Bayesian BMD software, which only recently became available.

The BMDL of 1.56 mg/L lies between the NOAEL of 1.3 mg/L and the LOAEL of 1.8 mg/L for moderate dental fluorosis in the Dean study.

Second, based on the weight of evidence to date, fluoride can credibly be considered to have an effect on childhood IQ. There is, however, significant uncertainty as to the POD. The draft NTP 2020 and 2022 reports concluded that evidence for effects below 1.5 mg/L was less consistent than that above 1.5 mg/L. Based on high quality MIREC and ELEMENT cohorts with individual-level measures, Grandjean and Colleagues (2022) <sup>[390]</sup> estimated the benchmark concentration for maternal urinary fluoride associated with a 1-point reduction in IQ. Different linear and non-linear models fit by Grandjean and Colleagues <sup>[390]</sup> resulted in benchmark concentrations differing by more than 9-fold. Although the NRC concluded that fluoride is an endocrine disruptor, leading to thyroid dysfunction at very low exposure levels among individuals with iodine deficiency <sup>[393]</sup>, the mechanism of action of fluoride for neurotoxicity is still poorly understood. Uncertainties in the shape of the dose-response curve at low levels of exposure to fluoride based on epidemiologic data will likely require extrapolation with a better understanding of the mechanism of action. For these reasons, a POD for IQ effects was provisionally selected as:

- 1.5 mg F/L, but acknowledging that credible support exists that the POD may be lower than this concentration (based on cohort data) and that the majority of studies to date

are cross-sectional studies with significant concerns regarding exposure assessment and potential confounding.

Consideration should also be given to the severity of the two end points - moderate dental fluorosis and IQ reduction – for which PODs have been derived. The choice of a BMR of 1 IQ point (corresponding to a 1% reduction from a mean IQ of 100) has been adopted as an appropriate benchmark on this endpoint by several regulatory bodies, including the US EPA and EFSA. This level of cognitive effect (in the context of assessing the exposure to lead) has been shown to be associated with reduced educational attainment, employment status, productivity, and earned wages, reflecting substantial public health concerns <sup>[391]</sup>.

Although outside of the scope of the present report, the establishment of an HBV for fluoride in drinking water will require consideration of possible adjustment factors to be applied to either of the two PODs derived above. Since the POD of 1.56 mg F/L for moderate dental fluorosis is based on high-quality population-based data in the target population (children), with only minor concern about other sources of ingested fluoride, a minimal adjustment factor could be entertained in deriving an HBV based on fluorosis. However, with currently available evidence suggesting that fluoride leads to reductions in children's IQ – arguably of more concern than moderate dental fluorosis – the possibility of cognitive effects in children should be taken into account in setting an HBV for fluoride in drinking water. As the POD for IQ reduction is not yet well defined, the POD of 1.56 mg F/L for moderate dental fluorosis may be preferred as a starting point for deriving the HBV. To allow for protection against potential cognitive effects in children at levels below the POD of 1.56 mg F/L, an additional overall database uncertainty factor could be applied to this POD.

As additional information on the association between fluoride in drinking water and reduction in children's IQ becomes available, the choice of the most appropriate endpoint on which to base the POD to serve as the starting point to deriving an HBV for fluoride can be revisited.

### **A better understanding of low concentration fluoride risks**

One of the challenges in evaluating the potential human health risks of fluoride is estimating risks at low levels of exposure. Following a comprehensive review of the scientific literature on health effects of fluoride in drinking water, neurological effects in children and dental

fluorosis emerged as the two key endpoints with exposure-response data suitable for determination of a point of departure for risk assessment purposes. Dental fluorosis demonstrates a very steep exposure-response curve, with risk increasing markedly between 1 ppm F in drinking water, at which there is a low risk of mild dental fluorosis, and 4 ppm, where there is a high risk of severe dental fluorosis. Reductions in children's IQ – the key indicator of neurological impairment noted in human epidemiological studies – demonstrated a shallower exposure-response relationship, with less evidence of the threshold-like behaviour seen for dental fluorosis. Considering the currently available evidence, possible fluoride effects on childhood IQ should be taken into consideration as an area of public health concern, although less consistent evidence at low exposure levels remains a source of significant uncertainty. Benchmark dose modeling of high-quality epidemiologic data by Grandjean et al. (2022) predicted increased risks at levels lower than 1 mg/L F in drinking water; however, different models – including linear, quadratic, and segmented models – predicted notably different levels of risk from fluoride at these low concentrations.

At this point in time, mechanistic explanation and key mode of action events are insufficiently understood to guide the choice of the most appropriate model to use for predicting risks at low exposure levels.

Given the challenges of using available epidemiological data to characterize potential fluoride health effects at low levels of exposure with a high degree of precision, an evaluation of the biological mode and mechanisms of action underlying fluoride toxicity was included in the current review to provide some guidance on extrapolation at low concentrations. Although fluoride was found to cause a number of biological changes through various toxicity pathways (including oxidative stress, changes in gene expression, mitochondrial dysfunction, ER stress, perturbation of the Na/K<sup>+</sup> ATPase pathway, apoptosis, inflammation, or death receptor-mediated pathways), the evidence from in vitro studies was considered to be too non-specific for health endpoints to, in particular, explain the occurrence of neurological effects in children following fluoride exposure. Absent a clear understanding of the underlying biological mechanisms and mode of action by which exposure to fluoride may act to reduce children's IQ, evidence for such effects below 1.5 mg/L remains uncertain. Experimental studies are needed to better understand the key mode of action events and their timing with respect to neurodevelopmental effects following maternal and early life exposure to fluoride <sup>[394]</sup>. Future

epidemiologic studies incorporating molecular and genetic components may also be of value in clarifying the shape of the exposure-response curve at low concentrations.
