1. ASSAY INFORMATION TC "ASSAY INFORMATION" \F C \L "2" |

RNP antigen is a 68 kilo-Dalton (kD) ribonucleoprotein. Anti-RNP antibodies react with proteins that are associated with U1 RNA and form U1snRNP. There is a high incidence of RNP autoantibody in patients with collagen diseases such as systemic lupus erythematosus (SLE) and mixed connective tissue disease (MCTD). MCTD (also known as Sharp's syndrome) is an autoimmune disease that is considered as an overlap of three diseases. SLE, scleroderma and polymyositis. SLE is a Type III hypersensitivity reaction caused by antibody-immune complex formation. It most often harms the heart, joints, skin, lungs, blood vessels, liver, kidneys, and nervous system. The course of the disease is unpredictable, with periods of illness (called flares) alternating with remissions. SLE occurs nine times more often in women than in men, especially in women in child-bearing years ages 15 to 35. Anti-RNP antibodies are detectable in 25-47% of SLE patients, most notably those of African descent. When present alone at high levels in blood, Anti-RNP antibodies are diagnostic of MCTD (with an incidence reportedly as high as 98.5%). Lower levels of anti-RNP, in conjunction with other autoantibodies, may be observed in scleroderma, Sjogren's Syndrome and Rheumatoid Arthritis. Anti-RNP antibodies are also more prevalent in patients with Raynaud's phenomenon and are associated with milder renal involvement

This assay is designed to qualitatively determine anti-RNP antibodies (Ab) in human plasma and serum using sandwich ELISA.

1.1.1 Reference Assays | TC "Reference Assays and Standards" \f C \l "3" |

The following commercial ELISA kits have been used in house as predicate methods:

- INOVA QUANTA Lite® RNP ELISA (Cat# 708565)
- Corgenix REAADS Anti-RNP ELISA (Cat# 10869)*
- IBL U1-RNP IgG ELISA (Cat# RE75211)

*FDA-cleared

1.1.2 Materials and Methods [TC "Materials and Methods" \f C \l "1"]

An RNP antigen coated surface serves as the capture surface for the RNP assay. The sample (plasma or serum) is diluted and incubated on the capture surface for 10 minutes. The surface is then washed to remove unbound proteins. An alkaline phosphatase (AP)-labeled anti-human IgG antibody is then incubated on the surface for 10 minutes. After the detection antibody incubation, another washing cycle is performed and the alkaline phosphatase substrate is incubated on the surface for 10 minutes, and the resulting chemiluminescence is read in Relative Light Units (RLU).

2 ASSAY DEVELOPMENT [TC "ASSAY OPTIMIZATION" \F C \L "2"]

2.1 Capture Surface Screen [TC "Capture Surface screen" \f C \l "1"]

The best capture surface for the anti-RNP assay was initially intended to be evaluated by comparing unlabeled RNP antigen capture surface to that of biotin-labeled RNP antigen surface. However, the RNP antigen (Arotec, CAT# ATR-0402) proved difficult to label via biotin conjugation. There was no protein recovery. Therefore, it was decided that capture surface would be best prepared with unlabeled RNP antigen through direct coating.

2.1 Capture Surface Titration [TC " Capture Surface Titration " \f C \l "1"]

Unlabeled RNP antigen in CBC was titrated at four levels: 1, 2.5, 5 and 10 μ g/mL and tested against Biorad positive and negative controls, 1 pooled normal serum sample (tested negative for RNP antibody via all three predicate methods listed in section 1.1.1) and 1 clinical serum sample (tested positive for RNP antibody via all 3 predicate methods). The coating condition at 5 μ g/mL provided the highest modulation between the RNP positive clinical sample and the Biorad negative control, and therefore was selected as the final condition for the capture surface. Data is summarized in Table 2.

2.2 Detection Antibody Screen

Detection antibody screening was performed with three clones of anti-human IgG: Clone 1 (Novus Biologicals), Clone 2 (Southern Biotech) and Clone 3 (Southern Biotech). All three clones were conjugated to alkaline phosphatase (AP). The clone 2 provided the highest modulation between the commercial negative control and the RNP positive clinical serum. However, its background signal is excessively high as observed by both the Biorad negative control and Stanford normal. Therefore, clone 1, which afforded the next best modulation, was deemed the better option. Data is shown below in Table 3.

| Table [SEQ Table * ARABIC] | . Det | ecti | on | An | tibe | ody Scre | en |

2.3 Effect of Alkaline Phosphatase Conjugate Stabilizer [TC "Effect of alkaline phosphatase conjugate stabilizer " \f C \l "1"]

Two commercial stabilizers (Biostab and StabilZyme) and one in house formulated alkaline phosphatase (AP) stabilizer were tested against the 3% BSA blocking buffer in TBS as detection antibody diluents, with the anti-human detection antibody (Dab) prepared at a final working concentration of 100 ng/mL. The Theranos-formulated AP stabilizer consisted of 3% BSA blocking buffer in TBS spiked with ZnCl₂ and MgCl₂ to achieve a final concentration of 0.1 mM Zn²⁺ and 5 mM Mg²⁺. The samples were diluted 1:25 into 3% BSA blocking buffer in TBS. Signal modulation was observed to be highest with both Blocking Buffer and Theranos AP Conjugate Stabilizer. However, for long term stability and storage, the latter proved to be a better choice. Therefore, Theranos AP conjugate stabilizer was finalized as the AP conjugate stabilizer for this assay. Data is captured in Table 4.

Table [SEQ Table * ARABIC]. Effect of AP Conjugate Stabilizers

2.4 Detection Antibody Titration

The AP conjugated detection antibody was evaluated in Biostab at four concentration levels: 25 ng/mL, 50 ng/mL, 100 ng/mL and 200 ng/mL. As suggested by the results shown in Table 5, the best modulation between the positive and negative controls was achieved with 100 ng/mL of the anti-human IgG detection antibody. It was therefore finalized as the final concentration of the detection antibody conjugate. Data is summarized in Table 5.

2.5 Effect of Assay Diluent

Two commercially available blockers (SuperBlock® and StartingBlock™) and one in-house blocking buffer spiked with 400 µg/mL of HBR were tested as diluents for the assay. Data was compared to the control diluent which was the blocking buffer consisted of 3% BSA and 0.05% sodium azide in TBS. The control condition produced the best modulation out of all the diluents tested with respect to the Biorad positive and negative controls. 3% BSA blocking buffer in TBS (without HBR) was therefore finalized as the diluent of choice for this assay. Refer to data in Table 6.

Table [SEQ Table * ARABIC]. Effect of Assay Diluent

Figure | SEQ Figure * ARABIC |. Effect of Assay Diluent

2.6 Effect of Sample Dilution

The effect of sample dilution was tested with final sample dilution factors of 1:10, 1:25 and 1:50 in blocking buffer consisted of 3% BSA and 0.05% Sodium Azide in TBS. Modulation between positive and pooled negative sera was greatest at 1:10. However, 25X also provided excellent modulation. 25X is preferred because higher dilution allows for more samples to be available in the event this becomes a part of a multiplex assay. Therefore, 1:25 dilution was chosen as the sample dilution for this anti-RNP assay. Results are summarized in Table 7.

Figure [SEQ Figure * ARABIC]: Effect of Sample Dilution

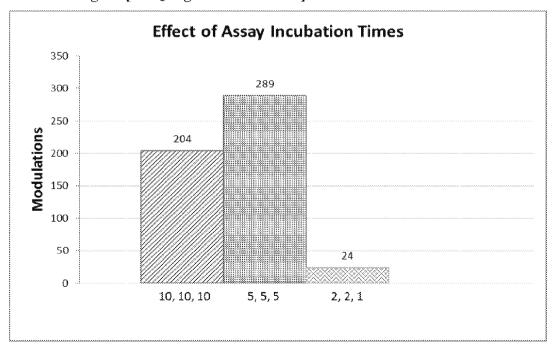

2.7 Effect of Incubation Time

The effect of shorter time to incubate sample, detection conjugate and substrate was evaluated at 5, 5, 5 and 2, 2, 1 minutes for comparison against the 10, 10, 10 minutes incubation time. Assay modulation between the RNP positive clinical sample and the Biorad negative control was almost similar between the 10, 10, 10 and 5, 5, 5 incubation times. However, 10, 10, 10 incubation time offered better modulation between Biorad controls. Therefore, it was selected as the final condition.

THERANOS CONFIDENTIAL Page [PAGE]

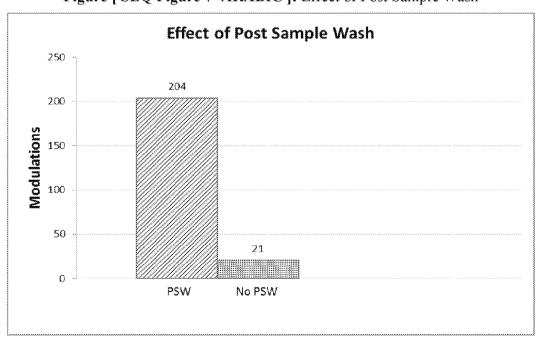

2.8 Effect of Post Sample Wash

The effect of a post sample wash was tested with the capture surface coated at $5 \mu g/mL$ (with Arotec RNP/Sm-free antigen), using a 1:25 sample dilution and detection antibody prepared at 100 ng/mL in Theranos AP Conjugate Stabilizer. The assay performed most optimally with post sample wash since this provided the best modulation between the commercial negative control and positive samples and afforded better precision. Data is shown in Table 9.

THERANOS CONFIDENTIAL Page [PAGE]

2.9 Normal Sample Screen: Cut-off Determination

Twenty-seven (27) randomly selected normal donor serum samples obtained from Stanford blood bank center and Bioreclamation were screened on the Theranos system to determine the cut-off value, which was calculated to be 181,078 RLU. The Theranos cutoff value was determined by taking the mean RLU of the 27 normal samples plus 5 times the standard deviation. The sample RLU divided by the cutoff value yields its Antibody Index. Samples are considered to be positive, borderline, or negative for RNP antibodies if their Ab Indices are found to be greater than 1.1, between 0.9 and 1.1, or less than 0.9, respectively.

Ab Index > 1.1
Ab Index > 0.9, < 1.1
Ab Index < 0.9

The same 27 samples were also screened using the predicate methods listed in section 1.1.1.

There was excellent correlation between Theranos results and those obtained from the predicate methods since all 26 samples tested negative across all platforms with one borderline. Table [SEQ Table * ARABIC]. Normal Donor Samples Screen on Theranos vs Corgenix, INOVA & IBL RNP ELISA

2.10 Specificity

Specificity relates to the ability of the test to identify negative results. It is the statistical probability that an individual who does not have the particular disease being tested for will be The specificity of this Anti-RNP assay, towards samples correctly identified as negative. containing antibodies specific for other ANA-related disorders, was tested on Theranos systems. Five RF positives, five HAMA positives, and positive controls for 11 ANA-related disorders from Centers For Disease Control (CDC) were tested. Of the 21 samples tested, four CDC controls (ANA Speckled, Anti-RNP, Anti-Sm and Anti-SSA) tested positive for this assay (data is summarized in Table 11). Ideally, none of the samples should test positive with the exception of the anti-RNP control. However, it is expected that Anti-ANA Speckled and Anti-Sm should test positive for this Anti-RNP assay because both of these CDC controls contain RNP. The Anti-SSA control however did not contain RNP but yet was tested positive on the Theranos systems. For this reason, additional screening with Biorad's Anti-SSA positive control was performed for confirmation, but result tested negative. To further demonstrate that this Anti RNP assay is not specific for Anti-SSA antibodies, one clinical serum that tested as a strong positive on the Anti-SSA assay was screened on the Theranos system using conditions finalized for the Anti-RNP assay. Data from the analysis for this clinical sample yielded very low titer for Anti-RNP antibodies which resulted in a negative reading under the Anti-RNP assay conditions. Based on this data, at least two conclusions can be made: (1) the positive test result of the CDC anti-SSA control is a false positive caused by an excipient(s) in its matrix that is unrelated to Anti-RNP antibodies, and (2) clinical sample that is specific for Anti-SSA antibodies will not test positive on this Anti-RNP assay. Therefore, this assay is considered specific only for Anti-RNP antibodies. The data generated as a result of troubleshooting "Specificity" are summarized in Table 12. Demographics information pertaining to the clinical samples tested are available in Table 14.

2.11 Clinical Sample Correlation

Clinical correlation assesses the accuracy of this anti-RNP assay with respect to the predicate methods listed in section 1.1.1. Randomly obtained normal and clinical serum samples were screened on Theranos system. Data is compared to those provided from screening the same set of samples via three commercial ELISA kits that are specific for the detection of RNP antibodies.

The commercial ELISA kits were obtained from three different vendors: INOVA Diagnostics, Corgenix and IBL International. 107 normal and clinical sera obtained from Stanford and Bioreclamation were collectively screened on these kits. INOVA, Corgenix and IBL each yielded 18, 17, and 14 positives, respectively, out of all the samples screened. Of the 107 samples, 20 of those samples screened positive on at least one of the three commercial kits (while only 13 of those samples tested positive on all 3 kits). All 20 samples that screened positive on any of the three kits (in addition to the 10 out of 15 normal Stanford sera) were screened on the Theranos system to evaluate clinical correlation. 8 out of the 18 clinical sera that tested positive for RNP antibody on the INOVA Scl-70 ELISA kit also tested positive on the Theranos system. One additional serum that tested positive on both the IBL and Corgenix RNP kits (but not on the INOVA kit) was also screened on the Theranos system. It was found to be negative, in correlation with the INOVA kit. Out of all the normal sera that tested negative across all three commercial ELISA kits, all also tested negative on the Theranos system. There was an approximately 62% correlation among the Theranos Anti-RNP assay and the 3 commercial ELISA kits data. This was calculated by taking the percentage of the number of positives yielded by the Theranos system (n=8) versus the number of positives agreed upon by all 3 predicate methods (n=13). However, only a small population of normal samples (27 total) was evaluated for cutoff (refer to section 2.9). Correlation between Theranos Anti-RNP ELISA and the predicate methods could be improved by screening more normal samples and re-calculating the cutoff based on a larger pool of normals. This will be further demonstrated during validation. See Table 10 for data from the normal donor sample screen on Theranos system in relation to the predicate methods. See Table 13 for a comparison of clinical correlation data between Theranos system and the predicate methods. Note that the normal Stanford sera (CLN1 to CLN10) were evaluated twice on the Theranos system on different days to provide data for: (1) normal screening (to determine cutoff) and (2) clinical correlation. Hence, Tables 10 and 13 contain different Theranos data sets for samples CLN1 to CLN10.
